THE EDITORS

Robert J. Stainton was introduced to philosophy of language and to linguistics (specifically in the Systemic Functional tradition) at Toronto's Glendon College. He completed his doctoral work in both areas at MIT. He has been Canada Research Chair in Cognitive Science at Carleton University in Ottawa, and is presently Professor of Philosophy and Associate Dean (Research) at The University of Western Ontario in London, Canada. His books include *Philosophical Perspectives on Language* and *Words and Thoughts*.

Alex Barber is Lecturer in Philosophy at the Open University. He works on the philosophy of language and linguistics as well as on various topics in other areas of philosophy, such as philosophy of mind, epistemology, and more recently, ethics. His published work includes papers on definite descriptions, opacity, speaker versus word reference, and syntactic reality, and various textbooks including *Language and Thought* (Open, 2005). He edited *Epistemology of Language* (Oxford, 2003).

SUBJECT CLASSIFICATION

Historical Foundations

Aristotle and Linguistics – P.A.M. Seuren
Boole and Algebraic Semantics – E.L. Keenan & A. Szabolcsi
Modern Linguistics: 1800 to the Present Day – R. Harris
Plato and His Predecessors – R. Bett
Plato's Cratylus and Its Legacy – J.E. Joseph
Saussure: Theory of the Sign – P. Cobley

Key Concepts from Linguistics for Philosophers

Anaphora: Philosophical Aspects – J. King
Creativity in Language – E.V. Clark
Deixis and Anaphora: Pragmatic Approaches – K. Green
Donkey Sentences – P.A.M. Seuren
Dynamic Semantics – J. Groenendijk & M. Stokhof
Event-Based Semantics – P. Lasnik
Evolution of Semantics – V. Evans
Evolution of Syntax – B. Clark & R. Jackendoff
Expressive Power of Language – D. Gil
Future Tense and Future Time Reference – Ö. Dahl
Game-Theoretic Semantics – J. Hintikka & G. Sandu
Generic Reference – G. Carlson
Grammatical Meaning – Ö. Dahl
Lexical Conceptual Structure – J.S. Jun
Lexical Semantics: Overview – J. Pustejovsky
Logical Form in Linguistics – D. Blair
Meaning: Cognitive Dependency of Lexical Meaning – P.A.M. Seuren
Meaning, Procedural and Conceptual – D. Blakemore
Meaning: Development – E.V. Clark
Modularity – R. Carston
Monotonicity and Generalized Quantifiers – R. Cann
Mood, Clause Types, and Illocutionary Force – K. Allen
Nonmonotonic Inference Origin of Language Debate – C. Neis
Plurality – P. Lasnik
Polysemy and Homonymy – A. Koskela & M.L. Murphy

Predication – S. Rothstein
Presupposition – P.A.M. Seuren
Quantifiers: Semantics – E.L. Keenan
Relevance Theory – F. Yus
Scope and Binding: Semantic Aspects – A. Szabolcsi
Semantic Value – J. Dever
Semantics of Interrogatives – B. Sherman
Syntax-Semantics Interface – J.-P. Koenig

Key Concepts in Philosophy of Language

A Priori Knowledge: Linguistic Aspects – G. Lavers
Action Sentences and Adverbs – D. Blair
Analytic / Synthetic, Necessary/Contingent, and *a Priori/a Posteriori* Distinctions – R. Elugardo
Anaphora: Philosophical Aspects – J. King
Assertion – M.S. Green
Causal Theories of Reference and Meaning – A. Sullivan
Character versus Content – C. Spencer
Communication, Understanding, and Interpretation: Philosophical Aspects – D. Hunter
Comparatives, Semantics – C. Kennedy
Compositionality, Philosophical Aspects – F.J. Pelletier
Compositionality: Semantic Aspects – G. Sandu & P. Salo
Concepts – E. Margolis & S. Laurence
Conditionals – S. Kaufmann
Context and Common Ground – H.H. Clark
Context Principle – R. Stainton
Conventions in Language – M. Kölbel
Cooperative Principle – K. Lindblom
Coreference: Identity and Similarity – Y. Huang
Counterfactuals – S. Barker
Creativity in Language – E.V. Clark
De Dicto versus *De Re* – E. Eaker
Default Semantics – K. Jaszczolt
Definite and Indefinite – B. Abbott
Definitions: Uses and Varieties of – G. Longworth
Deflationism – G. Marti
Deixis and Anaphora: Pragmatic Approaches – K. Green

Descriptions, Definite and Indefinite: Philosophical Aspects – G. Ostertag
 Direct Reference – A. Sullivan
 Donkey Sentences – P.A.M. Seuren

INTRODUCTION

The entries in this volume have been culled from Elsevier's fourteen-volume *Encyclopedia of Language and Linguistics*, 2nd edition (2006, ed. K. Brown). We have selected the topics that, in our view, are most likely to interest current or aspiring philosophers of language or those concerned with questions at the more philosophical end of linguistics. All but a handful of the entries we have settled on were new to that edition. The majority are from the Philosophy of Language section of the larger work, for which we were sub-editors, but around a quarter are from other sections. We have also been ecumenical in our interpretation of 'are most likely to interest'. Standard items you would expect to find in any list of topics *within* the philosophy of language or the philosophy of linguistics are, we trust, well represented. The volume extends well beyond these bounds, however, because we take the view that in order to do the philosophy of *x*, you need to know something about *x*, and often this means knowing what non-philosophers have to say about *x*. Thus alongside the explicitly philosophical entries are entries on topics that philosophers of language and linguistics are likely at some point to need to know about, despite these topics not being philosophical as such. (Indeed, we have gone so far as to include some entries that we think philosophers of language and linguistics *ought* to know about, whether they realise it or not.) So, for example, we have included entries on the more influential grammars, on comparatives, on what a word is, and so forth. We hope that readers will welcome having entries on such topics ready to hand, and will on occasion find themselves being drawn into reading up on topics they did not necessarily open the encyclopedia to find out about.

A word about the relation between philosophy of language and theoretical linguistics is in order. The last few decades have seen at least two fundamental changes: towards philosophy of language for its own sake, and towards the scientific study of ordinary talk. To understand these changes, it is vital to appreciate two corresponding background features of the philosophical landscape. First, for much of the twentieth century philosophy of language was regarded as the core field of philosophy in the sense that other fields were to be approached through its prism. In a weaker form, this is an old idea. But two schools in the twentieth century took this "linguistic turn" to a new level. This leads to the second background feature, namely the long-standing clash between "scientific" versus "actual usage" camps in the philosophy of language. Rudolph Carnap (1891–1970) and fellow logical positivists (see: 'Verificationism') regarded ordinary language as hopelessly inadequate to the needs of science, and so initiated the development of a new and better suited artificial language. Each sentence in this new language would be tied, definitionally, to the conditions under which it could be confirmed or refuted empirically. Anything not expressible in this improved language would then be dismissed as so much metaphysical nonsense. This revisionist project had been largely discredited by the 1960s, but it has cast a long and often unacknowledged shadow across the whole of philosophy. The opposing camp held that there was nothing wrong with ordinary language. Rather, philosophical problems arise when, to use Ludwig Wittgenstein's phrase, 'language goes on holiday'. Many followers of Wittgenstein (1889–1951), in common with the verificationists he and they opposed, regarded careful reflection on language as a route to overcoming philosophical confusion (see: 'Ordinary Language Philosophy').

The revisionist/scientific versus ordinary-usage dispute is represented in this volume. So too is the language-centric philosophical methodology advocated by both parties to that dispute. However, the ideas and methods of the two camps have gradually lost currency, and the relationship between philosophy of language and

linguistics has undergone a quiet revolution as a result. The focus of the volume lies here. Many theorists seek philosophical understanding of language for its own sake, rather than for the sake of generating a theory of language to serve the needs of other branches of philosophy. Part and parcel of this change has been a greater eagerness among philosophers over the past thirty or so years to have their opinions about language be informed by current approaches in theoretical linguistics. At the very least they are less dismissive than earlier generations were of the potential relevance to philosophy of language of empirical findings. That is, in what has been called the 'New Philosophy of Language', instead of seeing actual usage and scientific methodology as standing in opposition to one another, recent scholars have tended to adopt a scientific attitude to language *as it is*.

Such a philosophical study of language calls for a variety of skills, and is now generally acknowledged to be a collaborative endeavour. This is reflected in the coverage in the present encyclopedia. It is also reflected in the title, the relevant contrast being with *Concise Encyclopedia of Philosophy of Language*, the title of the parallel volume extracted from the first edition of Elsevier's *Encyclopedia of Language and Linguistics* (1993, ed. A. Kasher; the shorter work was edited by P. Lamarque and published in 1997).

Contributors to this encyclopedia have pitched entries at a level that caters to the needs both of relatively uninformed users and of those merely wishing for a sense of where things now stand in the relevant literature. For some topics more than others it seemed reasonable for collateral assumptions to be made about likely readers. For example, anyone looking up 'non-monotonic inference' is probably going to have some knowledge of more basic logical notions or to be willing to look these up. In contrast, many of those looking up the 'use/mention' distinction will have had relatively little exposure to either philosophy or linguistics, and the entry has therefore been written with them in mind.

There is some overlap in the entries, particularly those giving historical reviews of periods or topics. Since we do not envisage many users reading the encyclopedia from beginning to end, we see this duplication as harmless.

Readers looking for the views of a particular person are advised to use the index rather than the table of contents. The latter will make the coverage of key figures seem partial. We have included explicit entries on Plato, Aristotle, and Saussure, for example, but not on, say, Locke, Grice, or Chomsky. The explanation is simple. For the most part, we have taken a topic-based rather than authority-based approach, and the ideas of most key figures have been covered along the way. Locke's theory of language, for example, can be found in the entry on 'Ideational theories of meaning'. Individuals have an entry of their own only if their ideas are not covered in the topic-based entries.

We are hugely grateful to our contributors. All took the job seriously. Some worked to awkward deadlines, while others responded patiently to our occasionally pedantic suggestions. As a group they understood the nature and value of the project and made our job considerably easier than it could have been.

Alex Barber
Rob Stainton

A Priori Knowledge: Linguistic Aspects

G Lavers, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Immanuel Kant made two divisions between types of knowledge. He distinguished between the *a priori* and the *a posteriori* and also between analytic and synthetic judgments. *A posteriori* claims are the most simple to categorize: They include all empirical knowledge. Everything we learn about the world through our senses falls under this category. *A priori* knowledge is knowledge the ultimate justification of which is independent of experience. However, to call a piece of knowledge *a priori* is not to claim that the knowledge is literally prior to all experience (innate). For instance, mathematical knowledge is widely taken to be *a priori*. That is not to say that no experience is necessary to learn mathematical truths. When one claims that mathematics is *a priori*, this means that experience plays no role in the *justification* of a mathematical proposition. The justification and what led one to believe a proposition (the cause of the belief) need to be carefully distinguished. One may require paper and pencil to convince oneself that a certain mathematical proposition is provable. However, once proven, it is the proof and not the experience of the written proof that is the ultimate justification for the proposition.

A proposition is analytic according to Kant if it is true by virtue of meaning. For instance, the claim that all bachelors are unmarried is an analytic proposition because 'bachelor' just means unmarried man. For Kant and most of the analytic tradition in philosophy, all analytic truths are *a priori*. Because analytic claims are true in virtue of meaning, their justification is nonempirical.

Kant was of course familiar only with Aristotelian logic in which the only logical relation is that of containment between subject and predicate. He therefore equated the property of being true by virtue of meaning with being a logical truth in this sense. In the example above, for instance, it is true because the class of unmarried things includes the class of bachelors.

A proposition is analytic according to Kant therefore if and only if the subject concept is contained in the predicate concept.

Whereas all analytic claims are trivial, a synthetic claim is any claim that genuinely extends knowledge. All empirical claims are of this sort, but Kant argued that there were also nontrivial *a priori* truths. Kant held that the class of synthetic *a priori* truths included both geometry and mathematics. Mathematics is synthetic because, for instance, 12 is nowhere contained in the concepts of 7, addition, and 5. Mathematics is also *a priori* because it does not depend for its justification on experience. To show that (Euclidean) geometry must be *a priori*, Kant provided an argument that he called the 'transcendental esthetic.' Here Kant argued that geometrical relations cannot be learned through experience, because to understand something as located in space, we must have already organized our sensations spatially. That is to say, if our minds did not organize sensations spatially, we could not learn anything concerning the structure of space through sensation. This faculty of ours to organize sensations into a single Euclidean space Kant called our form of spatial intuition. That it is our minds that organize experience into a three-dimensional Euclidean space allows Kant to claim that even though geometrical claims are synthetic, they are nonetheless *a priori*. The structure of space is not learned from experience; it is known through the pure intuition of space. Our pure intuition of space is what allows us to have nontrivial *a priori* knowledge in geometry. Kant also argued that we must have a pure intuition of time because if we did not organize our sensations temporally we could not learn of temporal relations through sensation. It is this pure temporal intuition that Kant believed allows us to have synthetic *a priori* knowledge in mathematics.

Kant thought he had established that the laws of Euclidean geometry were synthetic *a priori* truths about empirical space. Yet, even as Kant was writing the arguments just presented, work was being done on the development of non-Euclidean geometries. Later, Hermann von Helmholtz showed that it is possible to imagine a set of experiences that would

2 A Priori Knowledge: Linguistic Aspects

lead one to believe that space is non-Euclidean. By the end of the 19th century, the geometry of our space was considered an open question. In Bertrand Russell's fellowship thesis, he argued that which geometry applies to our space is an empirical question.

Henri Poincaré took issue with Russell's assertion that the geometry of our space is a straightforwardly empirical question. If, for instance, we construct a large triangle out of light rays and then measure the angles and find that they do not sum to 180 degrees, we cannot yet say that the geometry of space is non-Euclidean. This is because, as Poincaré stressed, we require the further assumption that light travels in a straight line. Poincaré argued that, to preserve the simplicity of Euclidean geometry, we are free to postulate that the path of the light rays is not a straight line. He believed that we are free to hold either that light travels in a straight line and space is non-Euclidean or that space is Euclidean and light does not travel in a straight line. Given this situation, it is incorrect to say that space has a certain geometry. The question of the geometry of space is as meaningful as the question of whether space ought to be measured in inches or centimeters. The various geometries are purely abstract theories that say nothing about empirical space until certain stipulations have been made concerning the types of things that are to count as straight lines.

In 1915, Albert Einstein produced his general theory of relativity. This theory, which asserts that the curvature of space depends on the distribution of matter, is well confirmed. Furthermore, there is no flat space-time theory that makes the same predictions as general relativity. Given this situation, we are no longer free, as Poincaré assumed, to retain Euclidean geometry, come what may. However, Poincaré's point that, without intervening assumptions, geometrical propositions say nothing about empirical space still holds. We need to specify that the straight lines through space-time are the paths of freely falling bodies. It now seems clear that what Kant took to be synthetic *a priori* truths about empirical space are actually false. Hence, Einstein's famous quote: "As far as the laws of mathematics refer to reality, they are not certain; and so far as they are certain, they do not refer to reality."

The reaction in the philosophical community – especially the logical positivists in the early 20th century – to the situation just described was to reject the synthetic *a priori*. All *a priori* truths were taken to be analytic. This was motivated not only by the considerations above but also by the development of modern logic that expanded the class of logical truths significantly. Such a statement as 'if there is someone who knows everyone, then every one is known by at

least one person' can now be shown to be a logical truth, but it is certainly not a case of the subject being included in the predicate. Thus, the category of analytic *a priori* truths is expanded, and the class of synthetic *a priori* truths is eliminated entirely. The logical positivists also relativized the *a priori*. Any statement that we wish to hold as a matter of stipulation gains the status of an *a priori* truth. Definitions of theoretical terms or relations between theoretical terms can be taken to be *a priori*. If the theory that they are part of is modified or abandoned, they are no longer taken to be *a priori*. So, the class of *a priori* propositions is revised as we revise our theories.

According to the positivists, the model of scientific theories is as follows. Scientific theories are composed of a certain class of purely theoretical sentences that are taken to be analytic and *a priori*. Given that these claims are purely theoretical, they make no assertions about things that can actually be observed. This independence from anything observable explains their *a priori* status. These sentences are seen as true in virtue of meaning. However, there will also be a class of sentences that relate this theoretical vocabulary to things that can be observed. These are called 'correspondence rules.' These correspondence rules serve to give an empirical interpretation to the theoretical vocabulary.

This positivistic theory of theories came under heavy attack by W. V. O. Quine in the middle of the 20th century. In particular, Quine attacked the division of sentences into analytic and synthetic. For the positivists, given their rejection of the synthetic *a priori*, the rejection of the analytic/synthetic distinction amounts to a rejection of the *a priori/a posteriori* distinction as well. Quine thought that the difference between analytic and synthetic sentences is a matter of degree, rather than a difference in kind. His view was based on two observations. First, the distinction between observational and theoretical vocabulary is itself a difference of degree. Second, because we can reject highly theoretical sentences on the basis of making certain observations (if the theory as a whole is rejected), then it does not seem reasonable to claim that these sentences are independent of experience. For the positivists, such sentences as 'force equals mass times acceleration' function as a definition of force in Newtonian physics and are thus true in virtue of meaning, and hence, *a priori*. Yet, this claim, according to the positivists, says nothing about the world.

Quine stressed that individual sentences do not have identifiable content, but rather, it is theories as wholes that make assertions about the world. Thus, the definition of force, as part of Newtonian physics, does make an assertion about the world

(in this case, that the world is Newtonian). Quine's view that there are no analytic or *a priori* sentences was widely influential; however, there is now renewed interest in making the distinction between *a priori* and *a posteriori* assertions to better understand how scientific theories function.

Quine's attack on the analytic/synthetic distinction eventually faced empirical scrutiny. Linguists such as Noam Chomsky and Ray Jackendoff have shown that there are empirical reasons to hold that there is an analytic/synthetic distinction. Certain sentences seem to show analytic connections with one another. For instance, upon hearing the sentence 'Jane was convinced to leave' one will assume that Jane decided to leave. An analytic sentence is one whose truth is given by the existence of such a connection. Analytic sentences in this sense are true in virtue of meaning. They are also knowable independent of experience and thus *a priori*. However, that they are knowable independently of experience is not itself knowable *a priori* but known through empirical investigation of natural language. Kant imagined that we could identify *a priori* truths *a priori*. Here we have a case of *a priori* truths that are discovered empirically. On this view *a priori* truths can have no foundational epistemological status.

It had been almost universally believed that all analytic claims were *a priori*. This position is shared by Kant and the positivists (the positivists went further in claiming that all *a priori* claims were analytic). However, on the basis of work by Saul Kripke and Hilary Putnam, a case can be made that certain claims are both analytic and *a posteriori*. That is, there are

claims that are true in virtue of meaning, but are not knowable independently of experience. For instance, part of the meaning of the term 'water' is that it is composed of H₂O. So the sentence 'water is H₂O' is true in virtue of meaning, and thus analytic. However, this sentence is nonetheless a substantial claim about the world and certainly not knowable independently of experience, and thus it is *a posteriori*.

Action Sentences and Adverbs

D Blair, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Action Sentences

Philosophers have a long-standing interest in the distinction between the things that people do and the things that merely befall them. This interest stems from a deeper concern with the concept of intentional action and the nature of human agency. Many distinguished philosophers have sought to illuminate this distinction by looking at how actions are described in natural language and what such descriptions imply about the agents of an action and the role of their intentions in the events described.

It is difficult to get at the distinction in a principled way. The problem is especially acute for sentences like (1):

- (1) Phillip made Sally fall into the well.

Example (1) can be made true either by Phillip's deliberate pushing of Sally into the well or by his having accidentally done so. Likewise, a sentence such as:

- (2) John's hand rose

does not imply that the raising of John's hand was the result of anything that John did. Compare this with:

- (3) John raised his hand

which is true only if John intentionally raised his hand. Example (3), but not (2), implies that the

raising of John's hand was an **action** of his, that he intended to raise his hand and that this intention was the reason why his hand rose when it did. But does this difference in how the truth conditions of (3) might be constituted reflect a corresponding semantic difference? Is (3) actually ambiguous?

I will look at two popular ways of capturing the properties of action sentences, starting with one rooted in philosophical logic, the other more closely related to natural language semantics. One of the main traditions is tied to the logic of the deontic modalities, i.e., the logic of obligation. Just as one might translate sentences of the form α is *obligated to* Φ with a special operator with *It is obligatory for α that α Φ* , so one might capture the agentive sense of a sentence of the form α Φ -ed with *It was intentional of α that α Φ -ed*. Some other proposals for paraphrasing are illustrated in examples (4) and (5).

(4a) John swam the channel.

(4b) John brought it about that he swam the channel.

(5a) Sam brought the pie.

(5b) Sam made it the case that he brought the pie.

One can still wonder whether these paraphrases really capture the agentiveness of these constructions. Looking just at (4a), there are a number of ways in which one can bring about the swimming of the channel, not all of them having to do with one's intentionally swimming the channel. Similar remarks apply to *making it the case that*. Not all of what I can intuitively be said to have made the case originates in something I intended to do.

A notable development in this area, one which appears to escape some of the problems of earlier views, is the work Nuel Belnap, along with several colleagues. They treat

(6) John opened the door

on its agentive reading as equivalent to

(7) John saw to it that the door opened.

Adoption of a special operator *stit* (α sees to it that: p) also allows them to capture some of commonalities between action verbs and imperatives, e.g., the fact that imperatives can only be formed felicitously from action verbs. One might worry, though, about the relations the proposed paraphrases have to the meanings of natural language sentences.

Another, popular way of approaching action sentences comes from Donald Davidson. Rather than rendering action sentences in a notation specifically designed to capture the concept of intentional action, e.g., *stit* operators and the like, one seeks to illuminate the semantic properties of action sentences by looking at what a general theory of meaning for the language containing those sentences tells us.

More specifically, the signature move in Davidson's paper was to posit, alongside the overt arguments of the verb, an additional argument place whose value is an event. One natural way of capturing this thought is to look at ordinary ways of classifying objects. A common noun N predicated of an object x classifies x as an N – a chair, a book, etc. Likewise for verbs, if events are taken to be values of variables just as concrete objects are: a verb V predicated of an event e classifies e as a V-ing, e.g., as a pushing or a swearing, etc. The original formulation of Davidson's proposal, ignoring tense, is this:

(8a) John kissed Mary

(8b) $\exists e[\text{kiss}(\text{John}, \text{Mary}, e)]$

The extra argument place in (8b) is for an event. An early modification of Davidson's view is to make (8b) a bit more complex.

(8c) $\exists e[\text{AGENT}(\text{John}, e) \ \& \ \text{kiss}(e) \ \& \ \text{PATIENT}(\text{Mary}, e)]$

Informally, what this says is that there is a kissing whose agent is John and whose patient is Mary, i.e., there is a kissing of Mary by John.

Davidson's views have been influential, both in inspiring further work and in attracting critical attention. For example, what does one say about sentences like:

(9) I haven't eaten breakfast.

Surely, one does not want an utterance of (9) to mean that there is no past event of my having eaten breakfast. Views taking Davidson's work as a point of departure include the work of Jennifer Hornsby (1980) and George Wilson (1989). Pietroski (1998) and Lombard (1986) discuss some of other criticisms, suggesting modifications.

Adverbs

Adding events to the toolkit of philosophers and philosophically minded linguists also enabled new treatments of adverbs. There is perhaps no single reason why philosophers have been interested in adverbs. But a good deal of what is of interest to philosophers has to do with the metaphysics of events or, in terms that partly overlap with talk of events, occasions, happenings, situations, and states of affairs. For example, a good many philosophers have wanted to acknowledge different classes of events, e.g., states, processes, achievements, and so on. See Vendler (1967), Bennett (1988), and Steward (1997). One way to approach these issues is by looking at how adverbs modify verbs that apply to these different sorts of events.

I will look at two families of theories of adverbs, beginning with an application of Davidson's view

of action sentences. Just as adjectives modify nouns, so adverbs modify verbs. The following analysis is nearly unavoidable for many adjectives:

$$[_{NP} \text{Adj} [N]] \Rightarrow [\text{Adj}(x) \ \& \ N(x)]$$

Thus, the denotation of, e.g., ‘nice dog’ is something that is both nice and a dog. Davidson’s event analysis of action verbs gives a parallel, conjunctive analysis of adverbial modification:

$$[_{VP} \text{Adv} [V]] \Rightarrow [\text{Adv}(e) \ \& \ V(e)]$$

The grammatical combination of an adverb with a verb is to be interpreted as the predication of two predicates about an event. The parallel with nominal modification is preserved. The theory also works for phrasal modification of verbs, e.g., for prepositional phrases such as *in the school*, *at five o’clock*, *after he took the kids to school*, etc. A sentence such as (10a) is represented as (10b):

- (10a) Sam sang loudly in the shower
 (10b) $\exists e[\text{AGENT}(\text{Sam}, e) \ \& \ \text{sang}(e) \ \& \ \text{loud}(e) \ \& \ \text{in the shower}(e)]$

In words: there was a singing by Sam in the shower and it was loud.

Any theory of adverbial modification should show why the following inferences are valid:

- (11) Sally broke the eggs quickly in the sink
 (12) Sally broke the eggs quickly
 (13) Sally broke the eggs in the sink
 (14) Sally broke the eggs
 (15) Sally broke something in the sink.

Example (11) logically implies (12) and (13), both of which imply (14). Additionally, (11) and (13), although neither (12) nor (14), imply (15) by themselves. A large number of adverbial modifiers permit detachment inferences. These inferences are immediate on the event-based theory.

Even with these virtues though, Davidson’s theory does not readily extend to adverbs such as *halfway* or *partly*, e.g.,

- (16) John walked partly to the store
 (17) Alex halfway filled the glass with juice.

It does not seem to make any sense to talk about events that are, for example, halfway in and of themselves, although there are events that are halfway fillings of glasses. It seems as though the adverb forms up a complex predicate with the verb rather than standing alone as a predicate of an event. More seriously though, as easily as the theory handles cases such as *John swam quickly to the shore*, there is no obvious way of extending it to *John allegedly climbed*

the garden trellis. There is no event that is both alleged as well as a climbing. See Larson (2001) and Taylor (1985) for further discussion.

Perhaps the most influential way of treating adverbs is to take them to be quantificational in some respect or as forming up intensional operators (Cresswell, 1986 Lewis, 1975). This helps with sentences such as (18) and (19).

- (18) John probably left in a hurry.
 (19) George frequently left a chocolate on his son’s pillow.

Here, an adverbial appears to modify not the event picked out by the predicate, i.e., the leaving, but the whole proposition, i.e., John’s leaving in a hurry. A theory having only events at its disposal is ill equipped to handle these cases. On the other hand, a theory incorporating propositions and intensions and quantification over possible worlds seems to be in comparably better shape to handle these kinds of contexts.

Further, if one treated adverbs as properties of events, it is much easier to treat sentences that contain negations such as the following:

- (20) Rob cleverly didn’t catch a fish.

Here, one might say that Rob’s not catching a fish has the property of being clever. Another important advantage of a view like this is that it affords a nice treatment of indefinite noun phrases such as *a fish* or *a chocolate* in the scope of an adverb such as *frequent*. This can be seen in sentence (19) or in (21) and (22) below:

- (21) Lisa often found a missing check in the Chairman’s desk
 (22) Alex repeatedly felt an odd tickle on his toe.

Example (21) is perhaps best read as implying that it is often enough the case that Lisa, when looking in the chairman’s desk, found a check that was missing. And (22) is not best interpreted as implying that there is some one odd tickle that is felt repeatedly by Alex. Rather, what the sentence is most naturally understood as saying is that there was a set of odd tickles in Alex’s toe that was repetitive. The quantificational view is further developed by Thomason and Stalnaker (1975) and by McConnell-Ginet (1982).

Analytic Philosophy

M Beaney, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

'Analytic philosophy' is the name that is given to what is now generally regarded as the dominant philosophical tradition in the English-speaking world and increasingly in the rest of the world. In its widest sense, it might be taken to mean any kind of philosophy in which analysis plays a central role. But there are all sorts of kinds of analysis, and analysis – in one form or another – has been part of philosophy since the time of the ancient Greeks. Sometimes it is characterized in terms of the emphasis placed on clarity, rigor, and careful argumentation, often involving logical formalization. This might distinguish it from some types of 'continental' philosophy (as it is misleadingly called), to which analytic philosophy is frequently seen as opposed. But the best way to understand analytic philosophy is historically, as a movement that had its roots in developments around the turn of the 20th century and evolved in various directions in response to them.

The origins of analytic philosophy lie in the work of Gottlob Frege (1848–1925), Bertrand Russell (1872–1970), G. E. Moore (1873–1958), and Ludwig

Wittgenstein (1889–1951). In many ways, early analytic philosophy can be seen as comprising two main strands, one developing from Frege's logical analyses of number statements and Russell's theory of descriptions, and the other from Moore's concern with conceptual analysis in ethics and epistemology, the two strands synthesised to some extent by Wittgenstein in the *Tractatus* (1921).

Frege's Analysis of Number Statements

Central to Frege's logical analysis of number statements is the idea that number statements are assertions about concepts. A statement such as *Jupiter has four moons* is to be understood, not as predicating of Jupiter the property of having four moons, but as predicating of the concept 'moon of Jupiter' the second-level property 'has four instances,' which can be logically defined (cf. Frege, 1884: § 57). The philosophical significance of this idea can be illustrated by taking the case of negative existential statements (number statements involving the number 0), which have caused problems throughout the history of philosophy. Consider the following statement:

(U) Unicorns do not exist.

This statement is true, so it must clearly have a meaning. But what is it for (U) to have a meaning? If we analyze it in subject-predicate terms, in accord with its surface grammatical form, then ‘unicorns’ is the subject and ‘do not exist’ the predicate. But how can we say anything meaningful if ‘unicorns’ does not refer to anything? If unicorns do not exist, then what is it to which we are predicating the property of nonexistence? Should we posit – as Meinong and the early Russell did – the ‘subsistence’ of non-existent objects to act as the subjects of statements about them? On Frege’s account, however, such a statement is to be understood as asserting something, not about unicorns but about the concept of ‘unicorn.’ (U), in other words, really means what is better expressed as:

(U*) The concept ‘unicorn’ is not instantiated.

Interpreted like this, it can then be readily formalized in modern logic:

(U#) $\neg \exists x Fx$.

On Frege’s view, existence should not be seen as a (first-level) predicate, but instead, existential statements are to be analyzed in terms of the (second-level) predicate *is instantiated*, represented by the existential quantifier. To say that something does not exist is to say that the relevant concept is not instantiated.

Russell’s Theory of Descriptions

A similar strategy is employed by Russell in his theory of descriptions (1905). Consider Russell’s famous example:

(K) The present King of France is bald.

This too might tempt us to suppose that a king of France must somehow exist – or ‘subsist’ – in order to be the subject of such a statement. According to Russell, however, (K) is to be analyzed as (K*), which can then be formalized as (K#):

(K*) There is one and only one King of France, and whatever is King of France is bald.

(K#) $\exists x (Kx \ \& \ \forall y (Ky \rightarrow y = x) \ \& \ Bx)$.

Here there is no commitment implied to any non-existent objects. All that is needed to understand the statement is a grasp of the relevant concepts and logical constants (including the quantifiers). Definite descriptions, such as ‘The present King of France,’ on Russell’s view, are to be ‘analyzed away’: they do not have meaning in isolation (by standing for some object) but only in the context of the sentences in which they appear (sentences that have a complex, quantificational structure).

F. P. Ramsey called Russell’s theory of descriptions a ‘paradigm of philosophy’ (1931: 263), a view shared by both Moore and Wittgenstein. As Wittgenstein put it in the *Tractatus* (1921: 4.0031): “It was Russell who performed the service of showing that the apparent logical form of a proposition need not be its real one.” What both Frege’s and Russell’s logical analyses open up is a gap between grammatical (or apparent logical) form and (real) logical form. On the surface, both (U) and (K) seem to have a simple subject-predicate structure, but their underlying structure is more complex, revealed in (U#) and (K#). Generalizing, this suggests a whole program of analysis, the aim being to uncover the real logical form of the various statements we make, especially those that are philosophically significant or are liable to lead us astray. On Frege’s and Russell’s conception, then, analysis involves the rephrasing of problematic statements into ‘correct’ logical form.

Moore’s Conception of Analysis

Although Moore and Russell are often closely associated, and Moore endorsed Ramsey’s praise of Russell’s theory of descriptions (Moore, 1959: 195), Moore was less concerned than either Frege or Russell with the development of a logical system as a means to ‘correct’ ordinary language. Like the early Russell, in his own early work Moore assumed a crude decompositional conception of analysis. Propositions, for the early Moore, were complex concepts, and their ‘analysis’ simply involved their decomposition into their constituent concepts. But alongside this decompositional conception was a looser conception of analysis as clarification. This comes out in *Principia ethica*, in which Moore talks of ‘analysis’ as involving the distinguishing of questions that are misleadingly conflated, remarking that “the more clearly distinct questions are distinguished, the better is our chance of answering [them] correctly” (1903: 27; cf. vii). His later work is characterized by the careful and detailed – indeed, pedantic – attention he pays to the subtle distinctions of ordinary language in an attempt to resolve certain traditional philosophical puzzles, such as the problem of the external world (Moore, 1959: chapter 7).

Wittgenstein’s *Tractatus*

In the *Tractatus* (1921), Wittgenstein expresses his great debt to Frege and Russell but shares Moore’s view that ordinary language is in perfect logical order as it is and does not need ‘correcting’ (cf. 1921: 5.5563). What was needed was not an ideal

language but an ideal notation, revealing the underlying semantic structure of ordinary propositions no longer obscured by their surface syntactic form. The aim of analysis was to uncover the necessary presuppositions of our use and understanding of ordinary language. Notoriously, on Wittgenstein's early view, the logic of our language required the necessary existence of simple objects, a view he was later to repudiate as part of his general critique of the Tractarian picture theory of language and logical atomism.

Logical and Metaphysical Analysis

The early 1930s marked the heyday of the form of analysis embodied in Wittgenstein's *Tractatus*. During this period an important distinction came to be drawn between what was called 'logical' or 'same-level' analysis and 'metaphysical' or 'reductive' or 'directional' or 'new-level' analysis. The first translates the proposition to be analyzed into better logical form, while the second exhibits its metaphysical presuppositions. Take Russell's theory of descriptions again. In offering (K#) as the analysis of (K), the definite description is 'analyzed away': this is logical analysis, revealing the underlying structure of the statement. But once we have (K#), we must still explain the commitments that remain – to the relevant logical constants and concepts. This may in turn require further analysis to 'reduce' them to things of our supposed immediate acquaintance – such as the 'sense data' to which Russell himself appealed.

Ordinary Language Philosophy

During the 1930s, however, metaphysical analysis came under increasing fire, the assumptions of logical atomism being found unsupportable – in particular, the commitment to such things as simple objects or sense data. But this still left logical analysis – combined now with conceptual or linguistic clarification rather than metaphysical reduction. Wittgenstein himself gave up the idea that Fregean logic provided 'the' logic of ordinary language, but he continued to explore the 'logic' – or what he now tended to call the 'grammar' – of our concepts. In this he influenced a whole generation of philosophers, particularly those dominant in Oxford during the 1950s and 1960s: Gilbert Ryle (1900–1976), J. L. Austin (1911–1960), Paul Grice (1913–1988), R. M. Hare (1919–), and Peter Strawson (1919–). Ryle, for example, explored what he called the 'logical geography' of our mental concepts in *The concept of mind* (1949), in which he introduced the important idea of a 'category-mistake.' According to Ryle, Descartes made a

category-mistake in treating the mind as some kind of spiritual substance, in just the same way as a tourist who asks where Oxford University is in Oxford makes a category-mistake. Austin, even more than Moore, saw philosophical clarification as requiring close attention to the subtle nuances of ordinary language, and his distinction between locutionary, illocutionary, and perlocutionary acts played a key role in the creation of speech-act theory. Grice's conception of conversational implicature, too, might be singled out as influential in the development of speech-act theory and, more generally, in the recognition of the pragmatic alongside syntactic and semantic dimensions of language use.

Strawson is perhaps the best-known representative of the ordinary language movement in 20th-century philosophy. His critique of Russell's theory of descriptions in 'On referring' (1950) is as much a classic as Russell's original 1905 paper. Even though Strawson's *Individuals* (1959) marked a return to metaphysics, it was a form of metaphysics that Strawson called 'descriptive' rather than 'revisionary,' aimed at clarifying our basic conceptual frameworks. In a much later work (1992), Strawson talked of 'connective' rather than 'reductive' analysis as being the methodology of philosophy, illustrating just how far 'analytic' philosophy has evolved since the heyday of logical atomism.

Logical Positivism and the Quinean Tradition

But ordinary language philosophy, rooted in the work of Moore and Wittgenstein, represents only one wing of 20th-century analytic philosophy. As indicated above, the other main wing is the tradition that has its roots in Frege's and Russell's logic and extends through the work of Rudolf Carnap (1891–1970), Alfred Tarski (1901–1983), Kurt Gödel (1906–1978), and the other logical positivists and mathematical logicians, to W. V. O. Quine (1908–2000), Donald Davidson (1917–2003), Saul Kripke (1940–), and others. In this branch of analytic philosophy, there is greater concern with technical matters of logic and with its further development and use in understanding basic semantic concepts such as truth, logical consequence, and necessity. Possible world semantics, originating in Kripke's early seminal papers on modal logic, is perhaps the best example of recent work in this tradition, although Davidson's development of Tarski's work has been crucial in the huge interest that there now is in theories of meaning. On the more informal side, Quine's critique of Carnap's analytic/synthetic distinction has been both influential and

controversial (Quine, 1951). Quine made this critique to show the essential continuity of philosophy and science, with a consequent rejection of the view that there is something distinctive about conceptual analysis. But recent years have seen various defenses – albeit in new contexts – of conceptual analysis, most notably by Frank Jackson (1998).

Analytic Philosophy Today

The two wings of analytic philosophy identified here represent, perhaps, the most important divide within analytic philosophy, a divide that was debated in Richard Rorty's classic collection of papers, *The linguistic turn* (1967). The tension between those who see philosophical progress as lying in ever more sophisticated logical, metaphysical, and scientific theories and those who see the task of philosophy as one of conceptual clarification rooted in ordinary linguistic practices has been a persistent theme throughout the history of analytic philosophy. If there is one insight that might be singled out as lying at the heart of analytic philosophy, then it is this: that our use of language is often 'systematically misleading,' to use Ryle's (1932) phrase. But responses to that insight have varied considerably. Analytic philosophy today is a broad-ranging and complex set of intertwining subtraditions whose unity is constituted less by any distinctive set of doctrines than by their shared history. Understood like this, despite suggestions by some that we have now entered a 'postanalytic' age, analytic philosophy can be regarded as stronger and healthier today than it has ever been in the past.

Analytic/Synthetic, Necessary/Contingent, and a *Priori/a Posteriori*: Distinction

R Elugardo, University of Oklahoma,
Norman, USA

© 2006 Elsevier Ltd. All rights reserved.

Three distinctions – necessary/contingent, *a priori/a posteriori*, and analytic/synthetic – mark three different contrasts. The *a priori/a posteriori* distinction marks an epistemological contrast between two different ways of knowing some proposition or two different ways of being justified in believing a proposition. The necessary/contingent distinction marks a modal contrast between different propositions. The analytic/synthetic distinction marks a semantic contrast between different sentences. Until the work of Immanuel Kant, the prevailing view was that either every truth is strictly necessary, *a priori*, and analytic, or it is contingent, *a posteriori*, and synthetic. Suffice it to say that things have gotten a lot more complicated since Kant. Many philosophers are even dubious about the reality of some or all of these distinctions. In this article, I will sketch the main ideas behind each dichotomy and note some points of controversy.

Necessary/Contingent Distinction

Necessity and contingency are said to be metaphysical properties of propositions, primarily *de dicto* modality. (For some general sources on the metaphysics of modality, see: Driver, 2002; Gendler and Hawthorne, 2002; Linsky, 1977; Loux, 1979; Lycan, 1994; Melia, 2003.) A proposition *P* is necessarily true just in case *P* is true and would have been true no matter how things might have been – the world could not have been such as to render *P* false. *P* is necessarily false just in case *P* is false, and it would have been false no matter how things might have been – the world could not have been such as to render *P* true. (Notice that we defined *de dicto* necessity in terms of possibility and negation: necessarily *P* =_{defn} ¬Possibly ¬*P*. We could just as well have defined *de dicto* possibility in terms of necessity and negation: possibly *P* =_{defn} ¬Necessarily ¬*P*. There is a sense, then, in which one cannot give a definition of an alethic modality that goes beyond this circle.) A proposition *P* is contingently true/false just in case *P* is true/false but could have been false/true (if the world had been otherwise in certain respects). The necessary/contingent distinction is therefore jointly exhaustive and mutually exclusive of every proposition that has a truth-value.

Sentences (1a), (2a), (3a), and (4a) are examples of necessary truths:

- (1a) $12 \times 2 = 24$.
- (2a) Gold has atomic number 79.
- (3a) Biological parents have at least one offspring.
- (4a) All dogs are dogs.

Sentences (1b), (2b), (3b), and (4b) are necessary falsehoods:

- (1b) $12 \times 2 = 25$.
- (2b) Gold is not an element.
- (3b) Some biological parents have no offspring.
- (4b) Some dogs have fleas and no dog has any fleas.

Sentences (1c) and (2c) are contingent propositions:

- (1c) Al Gore won the 2000 U.S. Presidential Election.
- (2c) Water freezes below 32°F.

Although (1c) is false, it might have been true if only Gore had received more electoral votes than Bush from the state of Florida. By the same token, although (2c) is true, it might have been false. After all, the laws of physics and chemistry might not have held to the extent and degree that they do. If they hadn't, then it would not have been true that water freezes below 32°F.

Not all necessary truths are of the same kind. For example, (2a) is a metaphysically necessary truth – it is metaphysically impossible that the atomic number of gold not be 79, i.e., nothing could possibly be gold unless it is an element whose atomic number is 79. Mathematical Platonists who regard numbers as mind-independent abstract objects view (1a) as being a metaphysically necessary truth. According to them, the number 24 could not possibly have been distinct from the number that is the product of 12 and 2, which is the number 24 itself, since nothing can possibly be diverse from itself. The basic idea is the same in both cases: certain statements about a mind-independent reality must be true because of certain metaphysical facts about that reality (as opposed to facts about how we think about it).

Sentence (3a) is said to be a conceptually necessary truth because the concept of being a biological parent includes, as one of its conceptual components, the concept of having a biological offspring. Sentence (3a) is not so much a truth about the world as it is a truth about the concepts we use in thinking about the

world. On this view, conceptual necessity is determined solely by the inferential relations that are (allegedly) constitutive of the contents of concepts that are so related. If lexical concepts have internal definitional structure, then (3a) is true by definition and thus, for that reason alone (according to philosophers like A. J. Ayer), it is a necessary truth (see Ayer, 1946).

Sentence (4a) is an example of a logically necessary truth, since it is an instance of the tautological schema 'All Fs are Fs,' which admits of no possible counterexample. A counterexample to that schema would be a case involving some F that was simultaneously non-F, which is a flat-out contradiction and thus impossible. Because they are not made true by any metaphysical facts about the world, logically necessary truths aren't metaphysically necessary. Nor are they conceptually necessary, since they are not made true by any facts about the (nonlogical) concepts we use to think about the world. They are necessarily true simply by virtue of their logical form.

The *a Priori*/a *Posteriori* Distinction

The *a priori*/a *posteriori* distinction is an epistemological distinction: it characterizes the way a proposition is known or the way a person is justified in believing the proposition. (For more discussion on the *a priori*/a *posteriori* distinction, see: Boghossian and Peacocke, 2000; Bonjour, 1998; Casullo, 1999; Casullo, 2003.) As Kant presents it, *a priori* knowledge is knowledge that one has independently of all possible sense experience. What makes *a priori* knowledge *a priori* for Kant is its universality – it is knowledge of that which constitutes the formal constraints on *all* possible human experiences – and its necessity. For Kant, knowing that every event has a cause is a case of *a priori* knowledge. By contrast, *a posteriori* knowledge is only possible through experience or introspection. For example, knowing that several hurricanes caused massive destruction throughout Florida in 2004 is a case of *a posteriori* knowledge; you couldn't know that proposition is true merely on the basis of rational reflection.

The evidential source of *a priori* knowledge is neither sensory perception, nor introspection, nor memory. For you to be justified *a priori* in holding a belief, it is enough that you rightly recognize the truth of your belief given only your conceptual grasp or understanding of the content of your belief. Your reason for belief has to emerge from rational reflection or from rational insight, assuming that you have a nonempirical faculty of intellection. *A priori* knowledge may require experience to provide the relevant concepts, but, given possession of the concepts, no further role for experience is required for having

a priori knowledge, except insofar as it can play a preservative role in the transmission of *a priori* justification from one source to another, e.g., testimony.

If *a priori* knowledge is genuine, then propositions (5a), (6a), and (7a) are examples of *a priori* knowable truths:

- (5a) The relation *x is taller than y* is asymmetrical and transitive.
- (6a) Whatever is colored is extended.
- (7a) Whatever is red all over is not blue.

In each case, you can know the truth of the proposition simply by grasping its content, reflecting on what would have to be the case for it to be true, and then coming to recognize that the proposition must be true given your understanding of its content. Empirical observation plays no justificatory role in one's being warranted in believing (5a), (6a), and (7a). Knowledge of propositions (1a), (3a), and (4a) above would also be *a priori*.

By contrast, knowledge of (5b), (6b), and (7b) is *a posteriori*, since one's intellectual grasp of their contents is insufficient to secure epistemic warrant; moreover, one needs empirical evidence in order to be justified in believing them:

- (5b) Yao Ming (the famous Chinese NBA basketball player) is taller than Danny DeVito (the popular film actor and comedian).
- (6b) That car has a black exterior and is compact.
- (7c) Some of these cardboard shapes are painted red on the facing side.

Whether there really is *a priori* knowledge is a matter of great debate. Rationalists and Kantians contend that some knowledge is *a priori*, while Quineans, who adopt a naturalistic approach to epistemology, deny the reality of *a priori* knowledge. (For more on this topic, see: Boghossian and Peacocke, 2000; Bonjour, 1998; Casullo, 1999, 2003; Devitt, 1994; Moser, 1987.)

It is quite natural to think that all and only *a priori* knowable propositions are necessary truths. For example, A. J. Ayer presents the following argument for their identification in Ayer (1946). First, if a proposition is *a priori*, then it can be known to be true independently of any experience of the world. But if that's true, then the truth of an *a priori* proposition must not depend on any contingent features of the world; otherwise, one would have to determine whether those features actually obtained in order to know whether the proposition is true – and then it would be an *a posteriori* proposition. Thus, an *a priori* proposition must be true no matter how

things might have turned out in the world, which is the mark of a necessary truth. Second, if a proposition is a necessary truth, then it is true independently of the way things are. In which case, sense experience cannot play any role in explaining how we can know that proposition since experience can only furnish information about how things actually are, and not about how things must be. So, a proposition is *a priori* if it is a necessary truth.

Although Ayer's arguments contain some questionable steps, his arguments are not wildly implausible. More importantly, they set up a major challenge to his empiricism. If, as he and Carnap (1956) claim, mathematical and logical truths are necessary, and hence *a priori*, then we can have nonempirical knowledge; but then we can have some nonexperiential access to certain substantive facts about the world. That conflicts with Ayer's and Carnap's view that sentences, including sentences that express the contents of our knowledge, can have meaning only by being verifiable in principle. Ayer and Carnap thought they could solve this problem by explaining an *a priori* and necessary truth in terms of a linguistic notion of analyticity, namely, a sentence that is true by definition (Ayer) or by linguistic convention (Carnap). The idea is that any sentence that is true by definition must be necessary because, contrary to appearance, it contains no information about the world anyway. At the same time, it must also be *a priori*, because to know the proposition that such a sentence expresses is simply to know the definitional meanings of the terms that make up the sentence, which is enough to know that the sentence is true; experience plays no additional justificatory role. As we shall see later, Quine argued that the Ayer-Carnap gambit ultimately fails. Let us turn, though, to Saul Kripke's view on the connection between the necessary/contingent and the *a priori/a posteriori*.

Kripke on the Necessary *a Posteriori* and the Contingent *a Priori*

As noted in the last section, the prevailing view among philosophers until the 1970s was that all and only necessary truths are *a priori* and that all and only contingent truths are *a posteriori*. Most philosophers have now abandoned the view, thanks largely to Kripke (1972/1980). According to Kripke, metaphysical necessity is not a criterion for the *a priori* since they track entirely different kinds of properties (alethic modal properties and epistemic properties, respectively) of different kinds of things (propositions/sentences and ways of knowing a proposition, respectively). So it should come as no surprise that both can sometimes come apart.

Kripke's example of a sentence that expresses a necessary *a posteriori* truth is 'Water is H₂O.' According to him, the terms 'water' and 'H₂O' are each **rigid designators**: they refer to their bearers in every possible world. Thus, 'water' rigidly designates water, and 'H₂O' designates rigidly the chemical substance that is composed of H₂O molecules. Given that water is chemically composed of H₂O molecules, the two terms co-refer in every possible world. There is no possible world in which something is identical to H₂O but isn't water, so 'Water is H₂O' is true in every metaphysically possible world. It therefore expresses a metaphysically necessary truth.

According to Kripke, that water is H₂O is a *posteriori* knowable. First, it is *a priori* and necessarily true that a substance's chemical composition is essential to it. Hence, anything that has the same chemical nature as water must of necessity be identical to water. However, we can't deduce anything about the actual particular nature of water from the concept of its being a chemical substance or from the concept of its having an empirical nature that is essential to water. We have to do some empirical investigation instead. Only when our best scientific theories have confirmed that the chemical nature of water is H₂O can we then be justified in believing that water is H₂O. Therefore, our knowledge that water is H₂O, which is a necessary truth, is *a posteriori*. In general, all true scientific identities are, for Kripke, necessary *a posteriori* truths. If Kripke was correct, then a proposition's being a metaphysically necessary truth doesn't entail that it is an *a priori* truth. (Some of Kripke's followers deny that necessarily true scientific identities are *a posteriori* knowable; see Salmon, 1993.)

Kripke also holds that some contingent propositions are *a priori*. He gives the example of a speaker who introduces the measurement term 'one meter' to pick out the actual length of a certain stick kept in the science museum in Paris at time *t* (call the stick 'Stick S'). The speaker stipulates, "Let 'one meter' designate the length of Stick S." In Kripke's example, the speaker uses 'the length of Stick S at *t*' to designate the actual length that S has at time *t*, (where *t* is the time of the speaker's utterance of her stipulation). The description used determines the reference of 'one meter' but not its meaning. Although 'one meter' rigidly designates a certain length in all possible worlds, which in the actual world happens to be the length of Stick S at *t*, 'the length of S at *t*' does not designate anything rigidly. For there are possible worlds in which, when heat is applied to Stick S at *t*, S is not one meter long at *t*. Hence, the stipulative definition, properly interpreted, does not say that 'one meter' is to be synonymous with 'the length of

S at t.' Rather, says Kripke, the speaker fixes the reference of 'one meter' by stipulating that 'one meter' is to be a rigid designator of the length that is the actual length of Stick S at t. Imagine now that the speaker goes on to assert, 'Stick S is one meter long.' According to Kripke, the sentence 'Stick S is one meter long' is true but not necessarily true, since S could have had a different length at t under appropriate stresses and strains, heatings or coolings. Consequently, the proposition expressed is contingent rather than necessary.

Kripke next argued that, since the actual length of Stick S was used to fix the reference of 'one meter,' the speaker knows automatically and without empirical evidence that S is one meter long. The speaker's very act of fixing the term's reference constitutes her non-empirical justification for her knowledge of said proposition; she does not have to appeal to any experience in order to know that the proposition she expressed is true. This is something, then, that the speaker who introduced 'one meter' in that way knows *a priori*. Thus, on Kripke's view, the speaker's utterance of 'Stick S is one meter long' expresses a contingent *a priori* truth. If Kripke is right, then a proposition's being a contingent truth doesn't entail that it is an *a posteriori* truth. (Not everyone agrees that Kripke's example is an example of a contingent *a priori* truth; see: Casullo, 1999; Moser, 1987; Soames, 2003.)

The Analytic/Synthetic Distinction

Immanuel Kant, who first coined the analytic/synthetic distinction in Kant (1781/1998), defined an analytic judgment as one whose predicate-concept is contained in its subject-concept. Analytic judgments are 'explicative' in the sense that they add nothing new through the predicate to the subject, e.g., 'all bodies are extended.' A synthetic judgment is one whose predicate-concept is not contained in its subject-concept. Synthetic judgments are 'ampliative' in the sense that they add information to the subject concept that is new and that no analysis could possibly extract from it, e.g., 'all bodies are heavy.'

Although Kant held that all analytic truths are *a priori* and necessary, he didn't think that all *a priori* truths are analytic in his sense, e.g., truths of arithmetic. For instance, according to Kant, in judging that 12 is the sum of 7 and 5, one does not think of 12 when one thinks of the sum of 7 and 5. To affirm that 12 is the number that 7 and 5 sum to, one must also imagine certain changes in time, namely, the successive addition of units, which (for Kant) was an intuition of time. Consequently, the judgment that 12 is the sum of 7 and 5 is ampliative and

is thus synthetic. It is also *a priori*, since the judged proposition is known independently of sense experience.

As many commentators have pointed out, Kant's characterization of the analytic/synthetic distinction excluded judgments that appear to be analytic even though they are not of the subject-predicate form, e.g., 'If Mary *persuaded* Susan to attend college, then Susan *intends* to attend to college.' A more inclusive account was therefore needed. (For a discussion of the history of the analytic/synthetic distinction, see: Coffa, 1991; Pap, 1958.)

Metaphysical Analyticity

Since Kant, philosophers have viewed the analytic/synthetic distinction as a semantic distinction between sentences rather than as a distinction between judgments of the subject-predicate form. The standard definition of analyticity is this: *A sentence is analytic if and only if it is true solely by virtue of the meanings (in other words, definitions) of its constituent terms.* Any true sentence that is not analytic is *synthetic*. For example, sentence (8) below is analytic because its truth-value is supposedly fixed entirely by its meaning and structure. By contrast, sentence (9) is synthetic because its truth-value is not fixed by its meaning and form alone; it also depends on how things are in the world it describes.

(8) All vixens are female foxes.

(9) All vixens are nocturnal predators.

Following Boghossian (1997), I will call the standard definition of analyticity 'metaphysical analyticity', since it is a metaphysical thesis about what constitutes a sentence's having the truth-value that it has. (There are some excellent out-of-print anthologies on the analytic/synthetic distinction: Sleigh, 1972; Sumner and Woods, 1969. Pap, 1958, is still one of the best sources on this topic even though it is dated.)

By our definition, an analytic sentence owes its truth-value entirely to its meaning and form irrespective of any worldly facts. Consequently, no such sentence can undergo a change in truth-value, from truth to falsehood, unless it also undergoes a prior meaning-change. If the sentence were to undergo a shift in meaning, then it would not be expressing the same true proposition as before, since any meaning-change would necessitate a change in the proposition it expresses. Therefore, no analytic sentence could ever be empirically refuted (assuming that there is no change in its meaning).

In his famous 1951 study, W. V. O. Quine argued that no sentence is immune to error (see also

Quine, 1991). On the contrary, every sentence is open to possible refutation without any prior change of meaning. Thus, Quine denied that there are any analytic sentences in the metaphysical sense defined above. Let us, then, turn to his argument.

Quine's Belief-Revisability Argument

To set the stage for Quine's argument, I will briefly review the main points at the end of Quine (1951). In that article, Quine took aim against the traditional empiricist's 'dogma' that each meaningful sentence has its own experiential confirmation conditions apart from any background theory. For the empiricists, most notably Ayer (1946) and Carnap (1956), all substantial knowledge comes from experience. For them, confirming a sentence is just a matter of having the appropriate sensory experiences, ones that would confirm the sentence to some degree of probability. Having the appropriate sensations is enough, then, to verify a single sentence; you don't need to assume the truth of any other sentence in order to verify it.

Quine rejected that last claim, since he agreed with Pierre Duhem that our beliefs make contact with experience as a whole, not individually; see Duhem (1914/1954). Call that the Quine-Duhem Thesis. Verifying a single sentence presupposes, then, a massive background of beliefs and default assumptions, which brings us to Quine's Confirmation Holism: *the evidential status of any one belief is fixed by its evidential relations to other beliefs, and their evidential status is in turn fixed by their evidential relations to many other beliefs, and so on for all of one's beliefs*. Thus, no single experience or group of experiences could ever refute or confirm a sentence independently of its evidential connections to many other sentences.

It follows from the Quine-Duhem Thesis and Quine's Confirmation Holism that revising any one belief will necessitate a wholesale revision of one's belief-system. Quine presented his famous "web of belief" metaphor in Quine (1951) to explain this idea more fully. The beliefs that form the center of the 'web' are the ones that are almost impossible to give up (classical truths of logic, mathematical truths). The ones at the extreme ends of the web are the ones that are very easy to give up (observational beliefs), and the ones in between are relatively easy/hard to give up (scientific theoretical beliefs). Still, any belief can be rationally given up or revised for the right price and, by the same token, any belief can be held tenaciously, come what may, but at a cost. What to revise will depend on how much it will cost to preserve the system with respect to its coherence, simplicity, predictive power, and elegance.

Belief-change, then, is solely a function of practical utility: change those beliefs that will require the least amount of changes in the rest of your belief-system while maximizing coherence, simplicity, etc.

Quine's Belief-Revisability Argument against the reality of analytic truths consists of just three premises. First Premise: Quine's Confirmation Holism – there are sentences that you hold true and sentences that you hold false, but in each case the support of your belief is a complex matter of the holistic evidential relations your sentence bears to many other sentences. Second Premise: if Quine's Confirmation Holism is true, then no belief or sentence is completely immune to revision; every sentence can be rejected under pressure from empirical evidence plus a concern for overall coherence. (Putnam, 1983, is an interesting objection to this premise.) Third Premise: if there are any analytic sentences as traditionally conceived, then they must be unresponsive to the world's input, and so immune to revision. Therefore: there are no analytic sentences as traditionally conceived.

Frege-Analyticity

A different conception of analyticity can be found in Frege (1968) and is one that is also discussed in Quine (1951): *A sentence is analytic if and only if either (i) it is a logical truth, or (ii) it can be converted into a logical truth by substitution of synonymous expressions, salva veritate, and formally valid inferences*. Clause (i) mentions a logical truth, which, according to Quine, is any true sentence that remains true under every uniform semantic interpretation and reinterpretation of its component, nonlogical, descriptive terms. Consider, for example, sentence (10):

(10) Every brother is a brother.

The nominal 'brother' is the only nonlogical descriptive term occurring in (10); (10) is true and it remains true under every possible, uniform, (referential) interpretation of the two occurrences of 'brother.' It is therefore a logical truth and thus analytic by clause (i).

Consider now sentence (11):

(11) Every brother is a male sibling.

Although (11) is true, it is not a logical truth, since one could consistently reinterpret 'brother' and 'male sibling' differently by assigning different extensions to them, resulting in a reading under which (11) is false. Still, it can be transformed into a logical truth by replacing 'male sibling' in (11) with its synonym 'brother,' which then yields (10). Thus, (11) is analytic by clause (ii) of our definition even though it is not a logical truth.

Nothing in this account entails anything about what constitutes the truth-value of an analytically

true statement. Nor does it entail any unrevisability claim. Thus, Quine's Belief-Revisability Argument does not apply to this form of analyticity, at least not in any obvious way. Again, following Boghossian (1997), I will call this general account of analyticity 'Frege-analyticity.'

Is there a connection between the *a priori* and Frege-analyticity? If *a priori* knowledge is genuine, then logical truths like (10) are *a priori* knowable. Having the appropriate sense experiences is necessary for acquiring the concept of dog, but beyond that no empirical evidence is needed to know that if something is a dog, then it is a dog. Grasping the conditions under which (10) is true suffices for knowing that it is true, regardless of whether there are dogs and regardless of whether one has observed any dog. (11) would also be *a priori* since mere rational reflection and understanding of what the two synonyms mean provides one with the sufficient warrant needed to be justified in believing (11), and hence in knowing (11) *a priori*. Generally speaking, if there are any *a priori* knowable truths at all, then all Frege-analytic truths are *a priori* knowable for the kinds of reasons just mentioned.

Not all *a priori* knowable truths are Frege-analytic, however. For example, we said earlier that (5a), (6a), and (7a) are *a priori* knowable:

- (5a) The relation *x is taller than y* is asymmetrical and transitive.
- (6a) Whatever is colored is extended.
- (7a) Whatever is red all over is not blue.

None of them is a Frege-analytic truth since none is a logical truth, nor can any of them be transformed into one by substitution of synonyms, *salva veritate*. If anything, (5a), (6a), and (7a) are examples of synthetic *a priori* truths, assuming that the distinction between Frege-analytic and Frege-synthetic truths is genuine, exhaustive, and mutually exclusive. This notion of analyticity won't be useful, then, to logical positivists who attempt to reductively explain all *a priori* truths in terms of analyticity.

There are Frege-analyticities if there are logical truths, which Quine admitted there are. That is important for two reasons. For one thing, as we saw, Quine thinks that any logical truth is revisable. If he is right, then some Frege-analytic truths are rationally revisable; in that case, his Quine's Belief-Revisability Argument won't apply to this kind of analytic truth. For another, Quine himself admits in Quine (1951) to having a clear idea of a logical truth whose meaning, but not its truth-value, is implicitly fixed by stipulative definition, even though he thinks that logical truths are open to possible rational

revision. It would be inaccurate to say, then, that Quine thought there were no analytic truths in any sense whatsoever. However, he did think that were sense in which there are analytic truths, namely, logical truths, is philosophically uninteresting and trivial, and is certainly not robust enough to erect a substantive epistemology of the sort that rationalists envision.

Quine also denies that there are Frege-analyticities of the second variety: sentences that can be transformed into logical truths by substitution of synonyms by synonyms. These are the ones that overlap with the conceptually necessary truths that Ayer and Carnap claimed we can know *a priori*, and quite cheaply, without sacrificing empiricism's main tenets about meaning or empirical content. Quine was dubious of conceptually necessary truths of any sort, so we should present his general argument for the denial of Frege-analytic truths of the second kind. (I count the following, along with Frege, as defenders of Fregean-analyticity, with their own nuanced views about synonymy and belief-revision: Chomsky, 1988, 2000; Katz, 1967, 1972, 1990; Putnam, 1962, 1965. Gilbert Harman and William Lycan are opponents of Frege-analyticity for largely Quinean reasons; see Harman, 1967a, 1967b; Lycan, 1994.)

Quine's Objections to Frege-Analyticity of the Second Kind

For Quine, the crucial question is whether we can explain synonymy without presupposing, either directly or indirectly, any notion of analyticity, given that we are trying to explain analyticity. In his 1951 study, Quine considers five analyses of synonymy and argues that they fail on independent grounds or they violate his noncircularity constraint.

The first proposal he considers was that two expressions are synonymous if and only if they have the same meaning. The problem is that the notion of two expressions having identical meanings is just as obscure and in need of explanation as the notion of analyticity. An account of synonymy that doesn't appeal to such mysterious entities as meanings is preferable to one that posits them.

The second proposal is that two expressions are synonymous just in case they can be mutually interchanged in any simple, **extensional**, sentence without changing its truth-value. This account fails to give a sufficient condition for synonymy. The predicates 'is a (normal healthy) creature with a heart' and 'is a (normal healthy) creature with a kidney' are true of exactly the same things. So, one could replace the former with the latter in sentence (12), resulting in sentence (13), without a change in truth-value:

- (12) Every creature with a heart is a creature with a kidney.
- (13) Every creature with a heart is a creature with a heart.

However, the two predicates are not synonymous, since (13) is supposedly analytic and *a priori* but (12) is neither.

The third proposal is that two expressions are synonymous just in case they can be interchanged in any **intensional** sentence without changing its truth-value. As Quine points out, the restrictive interchangeability criterion fails his first constraint. Consider sentences (14) and (15):

- (14) Necessarily, all and only brothers are brothers.
- (15) Necessarily, all and only brothers are male siblings.

According to the criterion, if 'brother' is synonymous with 'male sibling,' then (15) has to be true since (14) is. However, we can't determine whether (15) is true unless we first know whether the sentence 'all and only brothers are male siblings' is analytic. After all, the only reason one would have for thinking that (15) is true is if one believed that its embedded sentence expressed a conceptual truth. But to say that it is a conceptual truth that all and only brothers are male siblings is tantamount to saying that it is an analytic truth, which violates Quine's noncircularity constraint.

The final criterion for synonymy that Quine considered is this: two expressions are synonymous if they are interdefinable. Appealing to definitions is unhelpful since, as Quine noted, there are different kinds of definitions. For example, dictionary definitions are reports of prior synonymies, in which case the final criterion is circular, and thus trivial. Nor will it do to say, as Ayer and Carnap have, that a definition is simply a semantic rule or meaning postulate. By that understanding, two expressions are synonymous if and only if they are correlated with one another in virtue of some (non-empirical) semantic rule of the language. The label 'semantic rule' is arbitrary, implying only the appearance of a particular sentence (or a schema) under the heading 'Semantic Rules.' At best, a semantic rule of a language L can only specify which sentences (if any) of L have the honorific status of being analytic-in-L if there are any, but it won't help explain the absolute, nonrelativistic, sense of analyticity. Moreover, different sets of truths could have appeared under that heading without a change in the total set of truths in the language. Not only is the appeal to semantic rules and meaning postulates arbitrary and unmotivated, but also it cannot settle decisively the question of whether a

sentence like 'everything that is green is extended' is true by definition, or whether it expresses an important empirical truth about the world. Presumably it is one or the other, and it cannot be both. Since there are many borderline cases of just this sort, the Fregean analytic/synthetic distinction is unprincipled. On the assumption that his 'divide-and-conquer' strategy is successful, Quine concluded (Quine, 1951) that the notion of Frege-analyticity is empty and thus can serve no useful theoretical explanatory purpose.

Grice and Strawson (1956) is a famous response to Quine's argument; cf. Putnam (1965, 1970). According to Grice and Strawson, the terms 'analytic' and 'synthetic' must mark a genuine distinction, since they have a determinate philosophical use. Generations of philosophy students have learned these terms, and many of them can instantly recognize the real differences between the standard examples. Moreover, those who are adept in applying the distinction will agree about new cases. No doubt there will be difficult cases, as in 'everything that is green is extended' or perhaps 'all cats are animals,' but it does not follow that the analytic/synthetic distinction is not genuine. (Chomsky, 2000, makes a similar point.) The fact that there are borderline cases doesn't show that there are no clear cases of the distinction. Suppose there is no genuine difference in semantic status between analytic and synthetic sentences. Then there couldn't be any clear cases of analytic and synthetic truths or any agreement on the application of these terms to new cases. And yet, as they point out, even Quine would admit that a logical truth (e.g., 'all dogs are dogs') is analytic and not synthetic in some intuitive sense. According to Grice and Strawson, Quine's adequacy constraints on any plausible account of analyticity or synonymy are too stringent, unreasonable, and arbitrary; they have the undesired effect of rendering any linguistic elucidation of a group of family-related concepts impossible. In their view, Quine has only shown that no satisfactory analysis of analyticity has yet been provided, and not that no such distinction could be made. (Grice and Strawson never said what analyticity amounts to; nor did they show that the analytic/synthetic distinction is exhaustive.)

Until the late 1990s, much of the "analytic/synthetic" literature since the 1950s focused on the question of whether Quine succeeded in undermining the distinction. The prevailing view since Quine (1951) is that Quine did indeed win the battle, and that he also won the war against logical positivists, who tried to salvage empiricism while granting that we have knowledge of certain *a priori* necessary truths; see Soames (2003). Since the 1990s, there has been a resurgence of rationalism, and thus a reaction against

Quine's epistemology and his arguments against the tenability of any substantive analytic/synthetic distinction. The writings of Bealer, Boghossian, Bonjour, Katz, and Peacocke helped fuel this resurgence. I will conclude this article with Boghossian's main contribution to the analytic/synthetic debate.

Epistemological Analyticity

Paul Boghossian defends an epistemic notion of analyticity in the spirit, if not the letter, of Ayer (1946) (see Boghossian, 1996, 1997): *A sentence is analytic if and only if grasping what the sentence means suffices in one's being justified in believing in the truth of the proposition that the sentence expresses.* Ayer and Boghossian differ in their emphasis: Ayer explained the *a priori* in terms of a linguistic notion of analyticity, whereas Boghossian explains analyticity in terms of *a priori* justification. They also differ as to whether implicit definitions can literally determine the truth-value of a sentence: Ayer thought they can, but Boghossian does not. Boghossian's motivation for defending an epistemic account of analyticity was that he thought it had the best chance of explaining our having nonempirical knowledge of logical truths and logically valid inferences – assuming that the meaning of a logical constant is fixed by its conceptual role in formally valid patterns of logical inference, which may be something we can grasp by means of an implicit definition. (Boghossian thinks that, regardless of how one conceives of analyticity, one has no choice but to take analyticity as a genuine substantive property of certain sentences if one is a realist about meaning, which he is. For space constraints, I will sidestep the meaning/realism issue in this article.)

Suppose that you utter (16) and you go on to assert (17) (the example is from Lycan, 1994, although the main idea goes back to Ayer and Kripke):

(16) By 'veline' I shall henceforth mean 'a vegetarian cat.'

(17) All veline cats are vegetarians.

Then, just by virtue of grasping the content of your utterance of (16), which fixes the meaning of 'veline' in your idiolect, you are justified in believing that the proposition you expressed by your utterance of (17) is true. Hence, (17) (as tokened by you) is epistemically analytic.

Notice that, on Boghossian's epistemic account of analyticity, one can explain why such statements as (5a), (6a), (7a), (10), and (11), are *a priori*:

(5a) The relation *x* is taller than *y* is asymmetrical and transitive.

(6a) Whatever is colored is extended.

(7a) Whatever is red all over is not blue.

(10) Every brother is a brother.

(11) Every brother is a male sibling.

In each case, we have a *prima facie a priori* warrant to believe the proposition expressed because we have, in each case, a sufficient grasp of an implicit definition of an expression's meaning – either tacitly in our behavioral use of the expression or by way of an explicit stipulative definition. According to Boghossian, and apparently Kripke, our grasp of an implicit definition, which creates a semantic fact, constitutes our justification for believing the proposition expressed by the sentence containing the expression.

As Boghossian notes, Quine had no qualms about stipulative definitions if they are just arbitrary rules that implicitly define the meaning of a symbol. Thus, Quine could not object to the use of stipulative definitions *tout court*. He would object to the suggestion that stipulative definitions can literally create – by linguistic fiat or by linguistic convention – factual truths and valid inferences that are **unrevisable in principle**; see Quine (1935, 1960, 1966). However, Boghossian never claimed that implicit definitions determine the truth-value of a sentence or that they determine the validity of a logical inference. Rather, he claimed that implicit definitions literally create meaning-constituting facts the cognitive grasp of which sufficiently warrants semantic belief. If anything, they determine the proposition expressed but not the proposition's truth-value. Thus, as far as Boghossian is concerned, Quine's arguments (1935 and 1966) at best show that, contra Ayer and Carnap, implicit definitions cannot literally create truths by convention or by speaker intention. They don't show, argued Boghossian, that implicit definitions cannot have a meaning-constituting-factual role or an epistemic role in an explanation of *a priori* knowledge of logic.

Gilbert Harman, who defends the Quinean view, rejected Boghossian's epistemic account of analyticity and the role of implicit definitions in an explanation of *a priori* knowledge; see Harman (1996). According to Harman, grasping the contents of one's stipulative linguistic intentions can never warrant semantic belief. The reason is that meaning stipulations are just working assumptions that can easily be given up and, as such, they provide no evidence for anything. They can no more create epistemic warrant for semantic claims than they can create truth-values from scratch. See also Lycan (1994) for objections to Boghossian's view.

Readers can be assured that this debate will continue. We can look forward to more interesting discussions on the three distinctions discussed in this article.

Anaphora: Philosophical Aspects

J King, University of Southern California, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Anaphora is the phenomenon whereby an expression, which is called a **proform** (e.g., 'he' [pronoun], 'so' [proadjective]), is interpreted in light of another expression in its immediate linguistic context, which is called the proform's **antecedent**. In this article, I will confine my attention to anaphoric pronouns, since they are the instances of anaphora that are of most interest to philosophers and linguists. A simple example of an anaphoric pronoun is the following (where 'Rebecca' is the antecedent of 'she'):

- (1) Rebecca left and she was angry.

Simple instances of anaphora such as (1), in which an anaphoric pronoun has a referring expression as its antecedent, are not of much interest to philosophers and linguists. The reason is that such cases seem easy to understand. The anaphoric pronoun simply refers to whatever its antecedent does.

Another sort of case in which the behavior of an anaphoric pronoun is well understood, and hence not of much current interest to philosophers and linguists, is a case of the following sort (on the reading on which 'she' has 'Every professor' as its antecedent):

- (2) Every professor believes she is smart.

In such cases, it is widely held that the pronoun is functioning as a variable bound by its quantifier antecedent. Thus, (2) could be represented more perspicuously as:

- (2a) [Every professor: x][x believes x is smart]

where the third occurrence of 'x' corresponds to the pronoun. Since the pronoun behaves like a variable in predicate logic, and since the behavior of such variables is well understood, most philosophers and linguists do not worry about such cases.

The interest of linguists and philosophers in anaphora derives from the fact that there are instances of anaphora in which the anaphoric expression cannot be understood as an expression referring to whatever its antecedent does (as in [1]) nor as a variable bound by its quantifier antecedent (as in [2]). Let's call such cases instances of **puzzling anaphora**. The question then arises as to how puzzling anaphora should be understood semantically. As will be seen, there are a number of competing proposals. We shall discuss two kinds of puzzling anaphora here. The first instance of puzzling anaphora is a case in which a pronoun has a quantifier antecedent in another sentence. Anaphora of this sort is often called **discourse anaphora**. Here are two examples:

- (3) Few students passed the exam. They studied hard.
- (4) A woman is following Glenn. She is from the IRS.

For the moment, let's concentrate on (3). There are at least two reasons for thinking that the pronoun in (3) is not a variable bound by its quantifier antecedent. Both reasons are discussed by Evans (1977). The first is that such a treatment clearly yields the wrong truth conditions for examples like (3). If 'they' is a bound variable in (3), the two sentences of (3) together should be equivalent to:

- (3a) Few students: x (x passed the exam and x studied hard)

But this is obviously incorrect, since (3) entails that few students passed the exam, but (3a) does not (it would be true if many students passed, but few both passed and studied hard).

Second, it is generally thought that the scope of a quantifier cannot extend beyond the sentence in which it occurs. If that is correct, then the pronoun in (3) falls outside of the scope of its quantifier antecedent and so cannot be bound by it.

Further, the pronoun in (3) cannot be understood as referring to whatever its antecedent does, since its antecedent is a quantifier and not a referring term at all. Since the pronoun cannot be understood as a bound variable nor as an expression that refers to whatever its antecedent does, the question arises as to how we should understand it semantically.

A second kind of puzzling anaphora is called **donkey anaphora** and it comes in two varieties. The first I will call **conditional donkey anaphora**:

(5) If Sarah owns a donkey, she beats it.

(where 'it' is anaphoric on 'a donkey'). The second I will call **relative clause donkey anaphora**:

(6) Every woman who owns a donkey beats it.

(where 'it' is anaphoric on 'a donkey'). On the readings we are concerned with, neither (5) nor (6) is talking about any particular donkey, and so the pronoun 'it' cannot be a term referring to a particular donkey. Further, in the case of (5), all independent evidence available suggests that a quantifier cannot take wide scope over a conditional and bind variables in its consequent (*'If John owns every donkey_i, he beats it_i'). This suggests that the (apparent) quantifier 'a donkey' in (5) cannot bind the pronoun in the consequent. In addition, even if 'a donkey' could magically do this in (5), assuming it is an existential quantifier, we still would not get the intuitive truth conditions of (5), which require that Sarah beat every donkey she owns. Similarly, the independent evidence available suggests that quantifiers cannot scope out of relative clauses (*'A man who owns every donkey_i beats it_i'), and so again the pronoun in (6) is not within the scope of its quantifier antecedent and so is not bound by it. Thus, the pronouns in both conditional and relative clause donkey anaphora cannot be understood as referring expressions nor as bound variables.

So we have two kinds of puzzling anaphora, discourse anaphora and donkey anaphora. In neither case can the anaphoric pronouns be understood as bound variables or as expressions referring to whatever their antecedents refer to. The question is: how should we understand such cases of anaphora semantically? A number of theories have been developed to answer this question. Sketches of four prominent theories of puzzling anaphora are given here. Because the theories are technical and sophisticated, only the barest sketch can be given of them. Readers interested in more detail should consult papers cited in the bibliography.

The first theory of puzzling anaphora we will consider is **Discourse Representation Theory** or **DRT**. Though this name for the view comes from Kamp (1981), Heim (1982) independently developed a

very similar view. Here I will be neutral between the somewhat different Heim and Kamp formulations. DRT claims that the indefinites in discourse anaphora like (4) ('A woman') and donkey anaphora like (5) and (6) ('a donkey') are not quantifiers. Instead they are really predicates that introduce free variables. The anaphoric pronouns are variables in such cases too. The apparent existential force of the indefinite in (4) results from default existential quantification over free variables. In (5), the semantics of the pronoun interacts with the semantics of the conditional to yield the result that the sentence is true iff Sarah beats every donkey she owns. In (6), the quantifier 'Every woman' 'unselectively binds' both the woman variables in logical form and the variables introduced by 'a donkey' and 'it'. So in (6), the anaphoric pronoun is bound after all, but not by its antecedent ('a donkey').

Descriptive Approaches to anaphora have been formulated by Evans (1977), Parsons (1978), Davies (1981), Neale (1990), and Heim (1990). On approaches of this sort, anaphoric pronouns in puzzling anaphora in some sense are interpreted as definite descriptions. Thus, the pronoun in (4) is interpreted as 'the woman following Glenn'. Similar remarks apply to the pronouns in (5) and (6). Here different accounts are given as to why and how (5) and (6) are true iff Sarah/Every woman beats every donkey she owns. For example, Neale (1990) claims that in such cases, the pronouns are interpreted as 'numberless descriptions,' which are essentially universal quantifiers. This yields the truth conditions mentioned. For a different approach, see Heim (1990).

The Context-Dependent Quantifier Approach (CDQ) is formulated and defended by King (1987, 1991, 1994, 2005) and Wilson (1984). On this approach, pronouns in instances of puzzling anaphora are themselves quantifiers. The forces (universal or existential), restrictions (what the quantifiers range over – e.g., 'every student' ranges over students) and relative scopes are determined by features of their linguistic contexts. Thus, according to CDQ, the anaphoric pronouns in puzzling anaphora are contextually sensitive devices of quantification. The precise natures of the quantifiers they express are determined by features of their linguistic contexts. In (4), CDQ holds that the pronoun expresses the existential quantifier normally expressed outside of any context by the indefinite 'a woman following Glenn'. Similar remarks apply to (5) and (6), except that the semantics of the conditional interacts with the pronoun *qua* quantifier to get the proper reading of (5) (see King, 2005); and in (6), the pronoun *qua* quantifier takes narrow scope with respect to the universal quantifier 'Every woman' (because its antecedent does as well).

Finally, there are **Dynamic Logic Accounts (DL)** of puzzling anaphora, originally formulated by Groenendijk and Stokhof, (1991), with different versions put forward by Chierchia (1995) and Kanazawa (1994a and 1994b). The key claim of such accounts is that quantifiers can semantically bind pronouns even if those pronouns do not occur in their syntactic scopes. So, despite appearances, the pronouns in (4), (5), and (6) are semantically bound by their quantifier antecedents. DL also makes novel claims about the semantics of conditionals and universal quantification to get the truth conditions of (5) and (6) to come out right.

At this stage of inquiry, it is fair to say that there is no consensus on which of the above-mentioned theories is correct. Each of the theories faces some difficulties and it is difficult to determine which theory is most successful. It is to be hoped that future research will shed more light on the proper theory of puzzling anaphora.

Architecture of Grammar

R Kempson, King's College London,
 London, UK

© 2006 Elsevier Ltd. All rights reserved.

A grammar of a language is by definition a formal model of the properties of language that are intrinsic to the words of the language and the way they can be combined. There are then a number of choices to make:

1. Should the explanation be defined solely to reflect structural properties of language, or should those properties in some sense be correlated with the way language is used in speaking or hearing?

This is the issue of language competence and its separation from language performance.

There is another criterion which a grammar might be required to meet, which might seem like just another way of putting the same question, but is taken as requiring a different answer:

2. Is it enough to provide a formal account of language structure, or should a grammar reflect general cognitive underpinnings, with the theory of grammar seen as part of a theory of mind?

This is the question of language as formal system vs. language as part of cognitive psychology.

There are then two debates about the internal design of the grammar to be considered. The first concerns the status of semantics in the grammar; the second concerns the status of the lexicon and its relation to syntax:

3. Should the grammar define a direct relation between the expressions of the language, and the entities in the world they are used to talk about; or should interpretation for natural-language expressions be defined in terms of concepts that the words express?

4. Is there some central body of properties that constitute the syntactic system of language, to be defined independently of the words that make up

the language, or is the entire body of structural properties of language expressible as statements about words and their combinatorial properties?

These issues are not unrelated, as will emerge; but the following discussion takes these issues in turn, keeping them separate in so far as possible.

The Competence-Performance Divide

Even though interpretation of utterances invariably depends on the context in which that sentence is uttered, in seeking to explain natural language, linguists generally restrict their attention to those properties of language that are intrinsic to the words of the language and their mode of combination, defining grammars for individual languages to capture those aspects of sound-interpretation correlation that are not subject to variation context by context. This separation of linguistic analysis from any direct reflection of language as used in context led to what are called competence models of language (Chomsky, 1965, 1986, 1995). These define principles that determine the limits on sound-meaning correspondences both for any one language and for language in general; and they are articulated without consideration of any application in language use. Models of performance are then defined to articulate the mechanisms necessary to use such models in parsing and production (Fodor, 1981; Garrett, 2000; Gorrell, 1995; Levelt, 1989) and are taken to be dependent on the prior and independent articulation of such competence models. There is an immediate consequence to this separation. In virtue of the lack of direct correspondence between competence models and data culled from language performance, grammars can only be evaluated relative to a relatively abstract concept of data; and these data are judgements of wellformedness of sentence plus interpretation pairs as made by competent speakers of the language.

Grammars: Formal-Language Theory vs. Psychology

Reflecting such string-interpretation judgements, the architecture defined is modular, with more than one level of representation defined, in order to capture the distinct forms of generalization needed. Minimally, there are three kinds of generalization – phonological, syntactic and semantic – reflecting the existence of mappings from phonological form onto interpretation via some projection of intermediate structure, with the lexicon listing words with their phonological, syntactic, and semantic specifications. (Since not all languages are written, spoken language is taken

to be primary.) The number and nature of such levels and the relation between them is, however, subject to debate. The debate is founded in two distinct points of departure for defining a grammar formalism, two different ways, that is, of answering question (2), which require two different ways of answering question (3).

The Formal-Language Pattern

On the one hand lies the formal-language tradition in which an articulated purpose-built formal system devised for the formal study of some (natural) phenomenon has a defined syntax, with an associated mapping from each licensed string onto some subset of the phenomenon under analysis. In such systems, the commitment to defining a concept of denotational content for the expressions of the language is definitional: the expressions pick out the objects under analysis, their denotation, for that is what the formal language is designed to do. The concept of compositionality is also true by definition: the meaning of a compound expression of the language is exclusively determined by the meaning of the parts and their mode of combination. Natural languages have been treated in like manner, explicitly following the formal language pattern (Montague, 1974). Categorical grammars, in particular, are faithful advocates of this formal-language tradition. They add to the characterization of a grammar some presumed specification of phonological properties of the listed primitive terms, but otherwise preserve the general architecture of a pairing of strings and denotational contents, with syntax no more than a systematic procedure for constructing pairings of phonological complexes and denotational contents for progressively larger units from words to sentences, with syntax and semantics essentially in tandem (Moortgat, 1997; Morrill, 1994; Ranta, 1994; Steedman, 1996, 2000). As might be expected given the adherence to the formal-language pattern, comprehensive accounts of anaphora and attendant concepts of underspecification of denotational content are commonly not provided (though see Ranta, 1994 for a proof-theoretic reconstruction of context and anaphoric dependency), and advocates of categorical grammar formalisms generally do not evaluate their formalisms relative to criteria of psychological reality (though see Morrill, 2002 for exploration of using categorical-grammar constructs in the study of acceptability). Consequently, the categorical grammarian's answer to question (2) is to reject the need for cognitive underpinnings. And the answer to question (3) is that a direct mapping from natural-language expression to denotational content is central to natural-language grammar formalism.

The Language Faculty as a Subpart of Central Cognitive Systems

On the other hand, there is the psychology-based tradition, committed to the stronger form of answer to (2), and denying the formal-language stance on (3). Within the general cognitive-science perspective, processing of input stimuli by a cognitive system (seeing, hearing, smelling, etc.) involve special-purpose devices that enable internal representations to be constructed on the basis of which such input stimuli are assigned interpretation by the cognitive system, the human agent then using these internally constructed representations to reason to conclusions about what it is that he has seen/heard/smelled, etc. Minimally, on this view, modeling operations of the cognitive system involves defining a mapping from representations of those stimuli onto representations that are formulae of a deductive logical system (or systems), the internalized “language(s) of thought” (Fodor, 1983). The representation thus constructed as interpretation of the input stimulus may have to be assigned some denotational content underpinning the constructed interpretation depending on one’s theory of mind, but it is the representation itself that constitutes the interpretation of the processed stimulus. There is a second property of such input systems, which natural language illustrates well. In all cases of input to the cognitive system, there is a gap between the information derived directly from some low-level representation of the input stimulus and the interpretation assumed by the cognitive system to be derived from it. This gap, which is essential to the flexibility and finite resources of the cognitive system itself, is filled by some mode of so-called non-demonstrative reasoning using other information as made available in the context. This perspective on natural-language modeling provides a very different starting point from the formal-language tradition, presuming as it does on a mapping from one form of representation to another, of which the input forms are systematically less rich than the output forms. In natural languages, this is displayed by pronouns and elliptical constructions, which provide an input to the interpretation process that is systematically less specified than how they are understood on any occasion of their use, having to be enriched by information that context makes available, in order to establish what information the anaphoric/elliptical expression conveys.

Chomskian grammars are the major representative of grammars adopting the psychological tradition of representationalism broadly construed, with all concepts of interpretation for natural language string articulated only as logical form representations (at the defined level of LF, see Chomsky, 1986, 1995

and elsewhere). On this view, syntax is defined as the core computational system with the levels of phonological form (PF) and logical form (LF) constituting interfaces with external systems (phonetic and intensional/conceptual systems, respectively). Central to this system is the characterization of discontinuities observable in all natural languages in which some expression may be indefinitely far from some position in the string with which, for interpretation purposes, it needs to be paired. These are cited by Chomsky as evidence that natural languages are not perfect formal systems (Chomsky, 1995), this departure justifying the irreducibility in the grammar architecture of the computational (syntactic) system. In capturing the supposed independence of the language computational system from the external systems with which it is interfaced, the minimalist system nevertheless respects general cognitive assumptions in so far as the internal properties of the language module have to be defined to allow interaction with general cognitive processes through these interface levels. As we would expect, given these assumptions, the properties of anaphora and ellipsis construal that are articulated as within the grammar formalism are expressed as syntactic principles.

Combining Formal Language and Psychological Traditions

Outside the Chomskian tradition, the three major grammar formalisms, Head-Driven Phrase-Structure Grammars (HPSG; Sag *et al.*, 2003), Tree-Adjoining Grammars (TAG; Joshi, 1987; Joshi and Kulick, 1995) and Lexical Functional Grammar (LFG; Bresnan, 2001; Dalrymple, 2001), all adopt a mixed approach, articulating semantics in terms of denotational content, but nevertheless preserving some form of cognitivist perspective.

On the one hand, they reflect the formal-language tradition in assuming that a specification of denotational semantics for sentence strings is part of the grammar formalism. Even while respecting this assumption, they nevertheless depart from the restrictiveness of the syntax-semantics correspondence defined for formal languages. Building on the presumed independence of phonological generalizations from the remainder, they allow the independence of syntactic generalizations from the combinatorial system required for other levels. Grammar formalisms may be defined to allow an *n*-tuple of levels, each articulated with independent vocabulary and forms of generalization (see Dalrymple, 2001; Jackendoff, 2002), leading to the consequent challenge of articulating adequately restrictive correspondence rules between these independent levels (Dalrymple, 1999). Despite the

relaxation of the tight architecture of formal-language grammar formalisms, the assumptions of compositionality, broadly construed, are preserved, with each word being assigned some n-tuple of phonological, syntactic, semantic, morpho-syntactic, information-structure, etc. each of which is in the form of constraints on its combinatorial potential, which then unify with specifications assigned to its neighboring items according as their specifications are consistent. Hence the term “unification-based grammars.”

Notwithstanding their conforming broadly to formal-language assumptions, such grammars lay claim to assumptions of psychological reality not dissimilar to those laid out by Chomsky. In so far as they invoke a level of denotational semantics as part of the grammar formalism, however, they fail to be commensurate with the representationalist methodology. And some of them blur the competence/performance distinction in allowing a pragmatic component within the grammar formalism (Sag and Ginzburg, 2003), a problematic move, since pragmatics is the study of the general cognitive principles underpinning successful communication, hence not part of a natural-language grammar.

Issues of Grammar Design

The Status of the Lexicon

The different status of the lexicon in the overall system reflects the different importance assigned to the lexicon in the two traditions. Following the formal language tradition, categorial grammars, HPSG, and LFG are fully lexicalized, with the lexicon providing a list of input triples of phonological, syntactic and semantic specifications for each lexical entry, these constraint sets dictating the mode of combination of adjacent or otherwise co-occurring expressions in the phonological, syntactic and semantic domains, respectively. Earlier Chomskian paradigms assigned a smaller role to the lexicon, with syntactic principles determining the core computational actions that induce structure, hence in principle reflecting the psychological distinction between stored information to be retrieved from memory vs. on-line construction. Phonological and semantic interpretation processes were merely interpretive, interface, mechanisms applying to the two distinct types of output from the central syntactic device. The central status of syntax led to the Chomskian Principles and Parameters model of language being described as the T-model:

phonology ← syntax → logical form

Between the two extremes of full lexicalist and nonlexicalist approaches, TAG formalisms project,

for each word (lexical item) entered in the lexicon, a family of local structures is defined as a stipulated form of input, but the nesting of these into larger structures is the result of general tree-adjoining mechanisms. In minimalist approaches, the lexicon plays a greater role than in earlier Chomskian models, but nevertheless detailed lexical specifications are not formally articulated.

The Syntax–Semantics Debate and the Grammar–Parser Relation

The discussion so far has presumed on the distinctness of syntax and semantics. Upon the formal-language stance, these are by definition distinct, for one is a representation, the other, being denotational, is purely interpretive of such representations. Given the representationalist methodology, however, the question arises whether representations defined as the syntactic mechanism for natural-language grammars constitutes anything more than a mechanism for progressively building the conceptual representations that constitute an interpretation of the signal. With a shift of perspective to one in which grammar formalisms are defined to model the mapping from phonological signals onto a progressively richer conceptual representation following the time-linear dynamics of on-line processing (Kempson *et al.*, 2001; Phillips, 2003; Cann *et al.*, 2005), exactly this simpler stance becomes available, with the bonus of a much more direct reflection of language in use. What have been thought of as irreducibly syntactic generalizations, in particular the discontinuity effects made famous in Chomsky’s work as motivation for movement processes in syntax, become expressible as part of the progressive time-linear construction of the emergent conceptual representation. On this view, the architecture of the grammar formalism acquires a directional dynamics, with phonological specifications providing input to actions that induce the building up of conceptual representations, as determined jointly by contextually provided structure, lexical specifications, and general structure-building processes:

phonology → syntax → logical form

The syntactic mechanism becomes simpler because instead of inducing a distinct syntactic structure and articulating a mapping between syntactic and phonological representations on the one hand and between syntactic and semantic (i.e., conceptual) representations on the other (as in the T-model), there is only the progressive construction of conceptual representations from phonological input. But such a shift leads to a radical narrowing of the traditional competence-performance dichotomy, for the competence model

reflects the dynamics needed to model performance, and becomes directly embeddable into psycholinguistic models of the general cognitive system.

Summary

As these snapshots indicate, the architecture of the language faculty as defined in the various grammar formalisms reflect different claims about the status of language within an overall theory of mind. The significance of a parsing-directed design for natural-language grammars, introduced as a recent departure from orthodox assumptions, is that it leads to re-evaluation of the role of language in the theory of mind: any property of the architecture intrinsic to all natural language grammars is by assumption not merely a design feature of language itself, but a sub-part of a general theory of cognitive psychology and a reflection of the human capacity for language use.

Aristotle and Linguistics

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The study of language has always had two kinds of practitioners, the practical and the theoretical linguists. Aristotle was no doubt the first theoretical linguist (in addition to being the first in many other subjects), but he also contributed essentially to the development of practical linguistics. His role in the history of linguistics has been highlighted in a few publications (e.g., Seuren, 1998; Allan, 2004).

Aristotle was born in Stagira, in Ancient Macedonia, in 384 B.C.E. His father was the personal physician and a close friend of the king of Macedonia, Amyntas II. An exceptionally gifted boy to begin with, Aristotle joined Plato's Academy in Athens at the age of 17, to remain there until Plato's death in 347. Having been passed over as Plato's successor, he left Athens to live, first, in Asia Minor and then in Lesbos. In 343–342, Amyntas' son and successor, Philip II of Macedonia, invited him to come and teach his son Alexander, then 14 years old. This he did for 2 years. In 336, Alexander succeeded his father and immediately conquered the whole of Greece. Under

Alexander's political protection, Aristotle returned to Athens in 335 and founded his school of philosophy, the Lyceum. There he taught until 323, when news of Alexander's death reached Athens. No longer certain of Macedonian protection, he left Athens overnight and sought refuge in Chalcis, just north of Athens, where a Macedonian garrison was stationed. One year later, in 322, he died of an intestinal disease.

His first great contribution to the study of language—not often mentioned—is the fact that he demythologized language. Rather than seeing language as a magical instrument to cast spells, entrance people, and call up past, present, and future spirits, he saw language as an object of rational inquiry, a means of expressing and communicating thoughts about anything in the world. The 'semiotic triangle' of (a) language as the expression of (b) thoughts that are intentionally related with (c) elements in the world, famously depicted in Ogden and Richards (1923: 11), is due to Aristotle. This is Aristotle's most general and perhaps also his most important contribution to the study of language, even if it is not often mentioned by modern authors, for whom it has become a matter of course that language can be seen as a valid object of rational inquiry.

In a more analytical sense, Aristotle's role in the development of linguistics is in large part due to his theory of truth. For him, truth and falsity are properties of either thoughts or sentences. A classic statement is (*Metaphysics* 1027b25):

For falsity and truth are not properties of actual things in the world (so that, for example, good things could be called true and bad things false), but properties of thought.

A few pages earlier, he defines truth as follows (*Metaphysics* 1011b26):

We begin by defining truth and falsehood. Falsehood consists in saying of that which is that it is not, or of that which is not that it is. Truth consists in saying of that which is that it is, or of that which is not that it is not.

Here Aristotle introduces *not* as a simple truth-functional inverter of truth values: a toggle between true and false. This has momentous consequences.

Aristotle's truth theory is known as the correspondence theory of truth, in that it requires a correspondence between what is the case in the world on the one hand and what is said or thought on the other. To make this notion of correspondence more explicit, some form of analysis is needed. Aristotle made a beginning with that. He analyzes the 'world' as consisting of things that are named by any of the 10 categories substance, quantity, quality, relation, place, time, position, state, action, or affection (*Categories* 1b25–30). Within the category 'substance,'

there is a hierarchy from the primary substances (individual existing entities) through a range of secondary substances, from species and genus to any higher order. The secondary substances together with the remaining 9 categories are properties or things that things are ("everything except primary substances is either predicable of a primary substance or present in it"; *Categories* 2a33).

On the other hand, he analyzes sentences as resulting from the application of a *katêgoroumenon* (Latin *praedicatum*) to something. The something to which the predicate is applied he calls *hypokeímenon* (literally 'that which underlies'; Latin *subiectum* or *suppositum*). Primary substances (entities) can be the object only of predicate application – that is, can only be *hypokeímena* (*Categories* 2b39–40). All other things can be either *hypokeímena* or properties, denoted by a predicate. Yet in orderly talk about the universe, it is proper to take lower categories of substance as the things predicates apply to and reserve predicates themselves for the denoting of higher-order substances and other categories of being (*Categories* 3a1–5).

The combination of a predicate with a term denoting the *hypokeímenon* Aristotle calls *prótasis* (Latin *propositio*). A proposition is true just in case the property assigned to the *hypokeímenon* actually adheres to it; otherwise it is false. Moreover, a true proposition is made false, and vice versa, by the prefixing of *not* ("it is not the case that"). The term *prótasis* occurs for the first time on the first page of *Prior Analytics*, which contains his doctrine of syllogisms (*Prior Analytics* 24a16):

A proposition (*prótasis*) is an affirmative or negative expression that says something of something.

A proposition is divided into terms (*Prior Analytics* 24b16):

A term (*hóron*) I call that into which a proposition is analyzed, such as the predicate (*katêgoroumenon*) and that to which the predicate is applied.

One notes that Aristotle lacked a word for what we call the subject term of a sentence. During the late Middle Ages, the Latin *subiectum* began to be used in that sense—an innovation that has persisted until the present time (Seuren, 1998: 121–124).

This was the first semantic analysis of sentence structure in history, presaged by, and probably unthinkable without, Plato's incipient analysis of sentence meaning in his dialogue *The Sophist*. It is important to note that Aristotle's analysis of the proposition does not correspond to the modern syntactic analysis in terms of subject and predicate, but rather to what is known as topic-comment analysis. The identification of Aristotle's sentence constituent for the denoting of a *hypokeímenon* with "grammatical

subject,” characterized by nominative case, and of Aristotle’s predicate with “grammatical predicate,” may have been suggested by Aristotle, as when he says that a morphological verb “always is a sign of something said of something else” (*On Interpretation* 16b7). But it was carried through systematically a few decades after Aristotle’s death by the linguists of Alexandria, whose task it was to develop teaching material for the Egyptian schools where local children had to learn Greek in the shortest possible time (Seuren, 1998: 21–22). Unfortunately, this identification was, though convenient, rash and ill-considered. It persisted more or less unchallenged until the middle of the 19th century, when some, mostly German, scholars discovered that the Aristotelian subject–predicate distinction does not coincide with the syntactic subject–predicate analysis universally applied in linguistics. For in actual discourse, very often what should be the subject according to Aristotle’s definition is not the subject recognized in grammatical analysis, and likewise for the predicate. Steinthal, for example, observed (1860: 101–102):

One should not be misled by the similarity of the terms. Both logic and grammar speak of subject and predicate, but only rarely do the logician and the grammarian speak of the same word as either the subject or the predicate.... Consider the sentence *Coffee grows in Africa*. There can be no doubt where the grammarian will locate subject and predicate. But the logician? I do not think the logician could say anything but that ‘Africa’ contains the concept that should be connected with ‘coffee grows’. Logically one should say, therefore, ‘the growth of coffee is in Africa’.

Observations like this gave rise to a long debate, which lasted more than 80 years. At the end, it was decided to keep the terms subject and predicate for the syntactic analysis and speak of topic and comment for the semantic analysis in the Aristotelian sense (see Seuren, 1998: 120–133 for a detailed discussion).

Syntax, in the modern sense, is largely absent from Aristotle’s writings. He does, however, distinguish between different sentence types (*On Interpretation* 17a1–12):

Every sentence is meaningful, not in virtue of some natural force but by convention. But not all sentences are assertions, only those in which there is question of truth or falsity. In some sentences that is not so. Wishes, for example, are sentences but they are not true or false. We will leave all other sentence types out of consideration, as they are more properly studied in rhetoric or poetics. But assertions are the topic of the present study [i.e., logic]. The primary assertive sentence type is the simple affirmation, the secondary is the simple negation. All other, complex, assertions are made one by

conjunction. Every assertion must contain a verb or a conjugated form of a verb. For a phrase like “man” is not yet an assertion, as long as no verb in the present, past, or future tense is added.

Some word classes are already there. Thus, at the outset of *On Interpretation*, he defines *ónoma* (noun) as “a stretch of sound, meaningful by convention, without any reference to time and not containing any internal element that is meaningful in itself” (*On Interpretation* 16a19–21). *Rhêma* (verb) is defined as “that which, in addition to its proper meaning, carries with it the notion of time, without containing any internal element that is meaningful in itself; it always is a sign of something said of something else” (*On Interpretation* 16b6–8). In his *Rhetoric*, at 1406a19, Aristotle uses the term *epíteton* for adjective. All other terms for word classes are of a later date, with many of them having been created by the Alexandrian linguists.

The term *ptôsis* is found relatively frequently, in the sense of nominal or verbal morphological modification, as in *Categories* 1a13–15: “Things are said to be named ‘derivatively’ when they derive their name from some other word that differs in morphological form (*ptôsei*), such as the grammarian from the word *grammar* or the courageous from the word *courage*.” The literal meaning of *ptôsis* is ‘fall’ (Latin: *casus*). Its use in the sense of morphological modification is based on the metaphor that the word ‘as such’ stands upright (in the ‘upright case’ or *orthê ptôsis*; Latin: *casus rectus*). Its other falls are represented by forms that are modified morphologically according to some paradigm. The Alexandrians began to reserve the term *ptôsis* for the nominal cases of *nominative* (the form of your own name), *genitive* (the form of your father’s name), *dative* (the name of the person you give something to), *accusative* (the name of the person you take to court), and *vocative* (the name of the person you call). These terms smell of the classroom, not of philosophy.

Assertion

M S Green, University of Virginia, Charlottesville, VA, USA

Plato in such works as *Cratylus* takes a sentence to be a series of names. This view is untenable because it is not the case that in uttering a series of names one thereby says something either true or false. “Ephesus, 483, Neptune” says nothing either true or false. By contrast, an indicative sentence, such as “Ephesus was a large city,” is true, and it seems to include elements other than names. Aristotle seems to be making just this point when in *De Interpretatione* he remarks

Falsity and truth have to do with combination and separation. Thus, names and verbs by themselves—for instance “man” or “white” when nothing further is added—are like the thoughts that are without combination and separation. So far they are neither true nor false (1963: 16^a9)

Aristotle, however, does not distinguish in his use of “statement” among (1) the sentence used to express a proposition, (2) the proposition thereby expressed, or (3) the use of that proposition in the performance of a speech act, such as an assertion. These are three distinct phenomena, but it took over two millennia before the point was formulated clearly by the philosopher-logician Gottlob Frege.

According to Frege, a proposition (such as the proposition that global warming is accelerating) is an abstract object, the existence of which does not depend upon any mind grasping it or any sentence expressing it (1984). By contrast, a sentence expresses a proposition if it is indicative and meaningful. Unlike propositions, sentences exist only as part of a conventional linguistic system and so in a clear sense depend upon human activities. Nevertheless, one can utter a sentence expressing a proposition without making an assertion. One might utter such a sentence in the course of testing a microphone, or in rehearsing one’s lines for a play, or for that matter in investigating a proposition to see what its consequences are without endorsing it. For instance, one might put forth the proposition that global warming will cause the melting of Greenland’s glaciers to see what would follow (the submersion of Florida, etc.) without claiming that global warming will in fact go so far as to melt Greenland’s glaciers.

There are three distinct items then: an indicative sentence, a proposition expressed by that sentence, and the use of that sentence and proposition

expressed to make an assertion. ‘Statement,’ ‘claim,’ ‘judgment,’ and even ‘proposition’ are often used interchangeably among these three notions, and in the history of philosophy no small amount of mischief has resulted from such ambiguous usage. (For a trenchant discussion of such ambiguity, see Geach, 1972; on the distinction between illocutionary force and semantic content, see Green, 2000.)

Isolating assertions from propositions and indicative sentences is only the beginning of wisdom about the former. An assertion is a speech act. Just as one can make a promise by saying, “I promise to do so and so,” so too one can assert P with such words as “I hereby assert that P.” (Austin, 1962 placed assertion on his list of ‘expositives’; Vanderveken, 1990 locates assertion on his list of ‘assertives.’) Further, just as a promise can only be made if certain conditions have been met (you cannot promise to do what is obviously outside your control), so too an assertion can only be made under certain conditions. For instance, it is doubtful that you can assert what is obvious to both you and your audience to be false. An attempt to do so will most likely be taken facetiously. Further, Strawson (1950) held that a sentence can make presuppositions that if not met prevent that sentence from being usable for assertions. If Iceland has no monarchy, then according to Strawson my utterance of, “The present queen of Iceland is beautiful,” will fail to make an assertion in spite of the fact that I have in good faith uttered a meaningful indicative sentence.

To assert a proposition is at the very least to put it forth as true. Searle (1969) tried to capture this dimension by construing an assertion of proposition P as an “undertaking to the effect that P.” That may be a necessary, but is not a sufficient condition: My betting a large sum on P’s coming out true is an undertaking to the effect that P is true, but it is no assertion thereof. (For instance, if I bet on P without believing P true, I am not a liar; if I assert P under those conditions, I am.) Searle, however, elsewhere wrote that an assertion has word-to-world direction of fit. According to this conception, inherent in the practice of asserting is the norm that the speaker’s words are supposed to track how things are. This feature distinguishes assertion from, say, commands, the aim of which is not to track the world but rather to get the world (in particular, one or more of its inhabitants) to conform to what the command enjoins. Commands are thus commonly said to have world-to-word direction of fit.

This notion of word-to-world direction of fit may be elaborated further by the way in which one sticks

one's neck out by making an assertion. One who asserts a proposition P is right or wrong on the issue of P , depending upon whether P is true: one is right on that issue if P is indeed the case and wrong if it is not. In thus exposing oneself to liability to error on the issue of P , one is doing more than if one had just uttered a sentence expressing P .

However, liability to error on the issue of a particular proposition still does not distinguish assertion from other speech acts involving propositions. One who guesses that P is also right or wrong on the issue of P , depending on whether P is the case. How may we distinguish assertion from other proposition-involving speech acts? Williamson (1996) contended that one who asserts P is thereby open to the challenge, "How do you know?" This much may not be said of other proposition-involving speech acts. For instance, it would be inappropriate to respond to one who conjectures, guesses, or supposes for the sake of argument that a black hole inhabits the center of the Milky Way, with the question, "How do you know?" Unlike these other speech acts, an assertion purports to convey knowledge.

One who makes an assertion incurs a risk through the aforementioned liability to error and, if Williamson is correct, is exposed to a conversational challenge. What if such a challenge is made? According to the view of Brandom (1983, 1994), in that case its issuer is obliged to respond with reasons that would justify the contested claim. Those reasons might invoke items of experience or the authority of others. The issuer of the assertion might even show that the speaker raising the challenge is committed to that proposition by her own convictions. If, however, the assertor is unable to convince the interlocutor of the assertion, others will become unable to defer to his or her authority if their own assertion of that same proposition is challenged.

In light of incurring a risk of error and exposing oneself to a conversational challenge, it might seem that asserting is more trouble than it is worth. Yet, asserting is the bread and butter of conversational life, so it presumably has redeeming points. First, one whose assertions turn out to be reliably correct, or at least widely accepted, garners credibility. That in turn is a source of social authority: We look to reliable assertors to get things right. Second, it might be held that knowledge has intrinsic worth. Although making an assertion that is borne out is not a sufficient condition for knowledge (you might have gotten lucky or not have believed what you claimed), it is often associated with it. For this reason, getting things right by means of a correct assertion might be thought to be its own reward.

Third, an assertion that is not challenged, or is challenged but the assertor responds with an adequate defense of the claim, may be entered into conversational common ground. A conversation begins with a (possibly empty) set of propositions that interlocutors hold in common while being mutually aware that they hold this information in common. Among fans at a baseball game this common ground might include propositions about current weather conditions, the teams' score, and perhaps a few items in the current national news. Much more will typically be common ground among members of a tightly knit family, less among people waiting at a major bus terminal (Clark, 1996).

Let Σ_i be a commitment store for interlocutor i , containing all those propositions to which interlocutor i is committed. Where $1, \dots, n$ are interlocutors, we may define $\Sigma_{1 \cap \dots \cap n}$ as $\Sigma_1 \cap \dots \cap \Sigma_n$. Even if $P \in \Sigma_{i \cap j}$, it does not follow that P is in the common ground of i and j , for neither may have any commitments with regard to the other's commitment to P . Rather, where s_1, \dots, s_n are a group of interlocutors,

P is common ground among s_1, \dots, s_n (written $P \in \Sigma_{1 \dots n}$) iff

- (a) for all $s_i \in \{s_1, \dots, s_n\}$, $P \in \Sigma_i$, and for all $s_i \in \{s_1, \dots, s_n\}$, (a) $\in \Sigma_i$.

$\Sigma_{1 \dots n}$ will in general be a proper subset of $\Sigma_{1 \cap \dots \cap n}$. When s_1, \dots, s_n are engaged in a conversation and s_i asserts that P , then so long as no other member of s_1, \dots, s_n demurs, $P \in \Sigma_{1 \dots n}$. This may bring about progress on a question at issue (Where is the bus station?; or Why is the child ill?) or may aid in the elaboration of a plan (of getting to the bus station or curing the child), and it enables speakers at a later time to presuppose P in their speech acts. For instance, once it is common ground that the child's illness is viral, we may presuppose this fact, as shown by the acceptability of a remark such as, "Since antibiotics will be useless on her, we need to ease her discomfort some other way." The use of the phrase, "Since antibiotics will be useless on her," would be inappropriate if it were not already common ground that the child's illness is viral and that antibiotics do not treat viral infections (see Green, 2000 for a fuller discussion).

In addition to enhancing inquiry and planning and to laying the foundation for later presuppositions, an assertion may generate other pragmatic effects. For instance, one who asserts P may also suggest, insinuate, or implicate a distinct proposition through the meaning of what one says: If one asserts that Mary was poor but honest, the use of "but" suggests that there is some tension between poverty and honesty.

According to Grice's theory of implicature (1989), in that case one does not, however, assert that there is such a tension. Rather, what one asserts is true only in case Mary is poor and Mary is honest. Again, if someone asserts that Mary lost a contact lens, he or she will normally be taken to suggest that Mary lost one of her own contact lenses, rather than someone else's contact lens. This implicature, due not to the conventional meaning of any particular locution but rather to norms governing conversational practice, is also no part of what he or she asserts. When a speaker asserts P, he or she often means (specifically, speaker means) a good deal more without thereby asserting those other contents.

Assertions are not just beholden to the norm of accuracy about the world; they are also held to the norm of sincerity. One who asserts what one does not believe is a liar. By contrast, it is no lie conversationally to implicate what one does not believe. If in response to your question, "Where is Mary?" I reply that she is somewhere in Spain, I may implicate that I am in no position to be more specific. If in fact I do know that she is in Pamplona, I have been evasive, misleading, and perhaps even mendacious but no liar (Adler, 1997). Similarly an assertion of P, while representing oneself as believing that P, is not also an assertion that one believes that P. Were that so, one would literally contradict oneself in saying, "P but I don't believe that P." As G. E. Moore (1993) observed, however, although this utterance does seem absurd in some way, it is not a self-contradiction. What it says could well be true. Although an assertion of P is not an assertion that one believes that P, that assertion does express, manifest, or display one's belief that P. Current research is actively engaged with the relation between assertion and the states of mind that it manifests (Williams, 1996; Davis, 2003; Green and Williams, 2006).

Behaviorism: Varieties

P Poirier, Université du Québec à Montréal, Montréal, Québec, Canada

© 2006 Elsevier Ltd. All rights reserved.

The term ‘behaviorism’ refers to a family of doctrines that emphasize the importance of behavior over mind, or cognitive processing, in psychology, notably as its proper subject matter or its ultimate evidential basis.

Psychological Behaviorism

Early in the 20th century, James Watson wove together three 19th-century ideas – Darwin’s evolutionary theory emphasizing the physical as well as psychological continuity between animals and humans, Wundt’s experimental method in psychology, and James’s functionalist psychology – into both a method and theoretical overview for animal and human psychology. In 1913, he published what came to be known as the behaviorist manifesto, ‘*Psychology as the behaviorist views it*,’ which contained a number of distinct but related doctrines, three of which are of particular interest for the student of language: (1) the rejection of introspection as an experimental method, (2) the shunning of internal events, and (3) the emphasis on learning.

Rejection of Introspection as an Experimental Method

In the late 19th century, Wundt convinced psychologists that scientific work in their discipline must be experimental and quantitative, but like all 19th-century psychologists, he continued to work on psychology’s traditional object – consciousness – and to access it by the traditional route of introspection. Stirred by a growing methodological distrust in the value of introspective evidence, and emboldened by various successes in animal psychology in which introspective data were not available, Watson, trained as an animal experimenter, argued that consciousness and introspection were not a proper basis upon which to establish an experimental scientific psychology.

According to Watson, experimentation in psychology begins and ends with observable behavior, a methodological prescription that is sometimes called ‘methodological behaviorism.’ To this day, virtually all working psychologists, even those who see themselves as strong opponents of behaviorism, adhere to Watson’s methodological prescription. For this reason, it is better to reserve the term behaviorism for the other behavioristic doctrines present in Watson’s manifesto.

Shunning of Internal Events

If all internal events are characterized by the fact that they are conscious and accessible only through introspection, then Watson’s rejection of conscious experience as the object of psychology amounts to a rejection of all internal events from the scope of psychology. Indeed, we find in Watson’s writing a move from his initial 1913 doubts about the epistemic value of internal events (*qua* conscious events) to the full-fledged elimination of everything internal found in his 1924 monograph *Behaviorism*. However, the elimination of everything internal, a position we could call eliminative methodological behaviorism, which is one of the two main tenets most strongly identified with behaviorism today, is only one way to meet Watson’s methodological prescription. The other is to view internal events as theoretical constructs, the value of which flows from behavioral observations. According to this position, internal events can be posited as theoretical construct provided they are ‘operationally defined’ into behaviors. Few psychologists, even among those we would undeniably classify as behaviorists today, followed Watson’s shunning of internal events. Edward Tolman and Clark Hull, for instance, were much more ready to posit internal events (drives, internal maps, etc.) as intervening variables mediating the relation between stimuli and responses. Even Skinner found a heuristic place for internal events in his *Experimental Analysis of Behavior* (EAB), but reduced their epistemic value within psychology.

We can call this position, held by most behaviorists, ‘operationalist methodological behaviorism.’ In their

day-to-day practice, most psychologists today are operationalist methodological behaviorists. To see what distinguishes those operationalist methodological behaviorists we call behaviorists from those called, say, cognitive psychologists, one has to look at the third element found in Watson's behaviorist manifesto, the emphasis on learning.

Emphasis on Learning

Whereas the first two doctrines found in Watson's manifesto are methodological, the third is theoretical. The main construct on which Watson established his psychology is the reflex; indeed, he opened his 1924 monograph with an analysis of the yawning reflex. However, Watson recognized that basic reflexes, which are fixed and innate stimulus-response (S-R) dispositions, have insufficient explanatory power to account for the behavior of many animals, and certainly those that interested Watson: birds and mammals, including humans.

To achieve the necessary explanatory power, Watson turned to the work of Russian physiologist Ivan Pavlov (1927), who had recently won the Nobel Prize in medicine for his work on a type of learning called classical conditioning. Pavlov showed that, when the temporal contingencies are right, stimuli that are neutral to the organism can be paired with innate (or unconditioned) S-R dispositions so as to acquire the ability to trigger the reflexes' response. Once the new association is established, there is a new, conditioned S-R disposition in the organism's behavioral repertoire. Since so many of human behavioral dispositions are not innate, Watson hoped that classical conditioning would offer a means to account for what is typically human in human psychology. Note that Watson's emphasis on a learning mechanism does not make him an empiricist: indeed, for his own brand of behaviorism to get off the ground, he needs to posit a large number of innate unconditioned reflexes. With the development of the concept of operant conditioning, and to the extent he relegated classical conditioning to a secondary role, Skinner was actually much more of an empiricist than Watson ever could be.

Skinner developed both a school of psychological research – the Experimental Analysis of Behavior – and a philosophy to underwrite it, called radical behaviorism (Skinner, 1938, 1974). According to EAB, every behavior can be broken down into three parts: the discriminative stimulus (the type of situation the organism is in), the operant response (a response that can be modified as a function of its consequence), and another stimulus: the reinforcer

or punisher – an event that increases (reinforcement) or decreases (punishment) the probability that the organism will produce the operant response in the presence of the discriminative stimulus. Operant conditioning, a general learning mechanism, is said to have occurred when a stimulus has increased or decreased the probability that an organism will produce a given operant response when the discriminative stimulus is present.

Unlike Watson's elimination of inner mental states, Skinner's EAB did not shy away from them, but viewed them as operant responses, which could be reinforced or punished by stimuli. Contrary to psychological tradition, however, inner mental states were not seen as causes of behavior, but rather as behaviors (operant responses) in their own right, to be controlled by external stimuli like any other operant response. And unlike classical conditioning – the learning mechanism favored by Watson – operant conditioning is a *creative process*, much the same way natural selection is, allowing for the selection of new responses. Armed with operant conditioning and classical conditioning to a lesser extent, Skinner believed he could account for any human behavior.

In his discourse on method, Descartes famously set a limit on mechanistic explanation in psychology. No mere mechanism could, he believed, account for the productivity and pragmatic appropriateness of language and reasoning. In his 1957 work, *Verbal Behavior*, Skinner sought to show that, by applying the concepts and methods of EAB, one could mechanistically account for both the productivity and pragmatic appropriateness of language. His account of pragmatic appropriateness took sentences as wholes and showed how the environment, especially the verbal community, provides reinforcers and punishers to shape verbal responses. His account of productivity focused on words and attempted to show how sentences are structured by reinforcers and punishers provided by the child's verbal community.

In a famous review of Skinner's book, Chomsky (1959) attacked Skinner's behaviorist account of language. Chomsky set up a two-horn dilemma on which Skinner could only impale himself. Either Skinner uses EAB's theoretical terms in a strict and controlled way – that is, as he defined them operationally – or he interprets them in a loose and metaphorical way. If he interprets its terms in a loose and metaphorical way, then his analysis of language amounts to nothing but a disguised form of mentalism. On the other hand, if Skinner interprets EAB's theoretical terms as he defined them operationally, then, according to Chomsky, Skinner's behaviorism could not account for language.

Operant conditioning shapes verbal behavior by differentially reinforcing and punishing verbal output. One can easily see how this process could account for the pragmatic appropriateness of verbal responses in anyone who can produce them. (Chomsky did not emphasize this aspect of verbal behavior, perhaps because he himself did not have an account of pragmatic appropriateness.) However, according to Chomsky's famous "poverty of stimulus argument," operant conditioning cannot account for the acquisition of the capacity to produce grammatical verbal responses. The linguistic environment (the stimulus) is said to provide children with insufficient evidence – to be precise, evidence that was too *unsystematic* and too weak – to acquire the grammar of the language spoken around them: unsystematic because it contains no negative evidence (evidence that identifies ungrammatical verbal output as ungrammatical) and *weak* because positive evidence (evidence that identifies grammatical verbal output as grammatical) is of low quality. Moreover, because children hear only a small finite subset of all the grammatical sentences of their language, they cannot take the absence of a grammatical form as evidence of ungrammaticality. Yet, despite the poor nature of the stimulus they get from their verbal environment, children normally acquire their native language quite rapidly.

Over the years, every element of this argument has been argued extensively. Skinner himself never bothered to reply to Chomsky since it was obvious to him that Chomsky had not read his book. As noted, *Verbal Behavior* did in many ways offer an account of language's pragmatic appropriateness (one of Descartes' challenges to a mechanistic explanation of the mind), something that formal grammars cannot. However, Chomsky was right in claiming that Skinner's book offered no clue to the productivity of language (Descartes' other challenge), whereas his own did. One could say in retrospect that the score between Skinner and Chomsky is one-all. Nevertheless, by the 1960s, the tide had turned against behaviorism, and the time was ripe for cognitive science. Chomsky's attack on Skinner's *Verbal Behavior* was seen as one of the definitive moments in the birth of cognitive science.

Philosophical Behaviorism

Philosophical behaviorism is a semantic theory about the meaning of mental statements; that is, statements used to attribute mental states to oneself or another. Although philosophical behaviorism generally is often identified with the particular brand developed

by neopositivists, it is important to note that it has three main strands. They are, chronologically, the reductionist philosophical behaviorism of the Vienna Circle and two related but distinct responses to it: the nonreductionist philosophical behaviorism of ordinary language philosophers and the eliminativist philosophical behaviorism of Quine. All of these positions are behaviorist in that they posit a special relation between behavior or behavioral statements and the meaning of mental statements. What distinguishes the three is the type of relation they posit.

Reductive Philosophical Behaviorism

Developed by members of the Vienna Circle as part of their unity-of-science program, reductionist philosophical behaviorism (also called logical or analytical behaviorism) posits that there can be semantic identity between mental statements and (a finite subset of) behavioral statements. Two specific neopositivist theses are at the heart of this approach: (1) positivism – the rejection, as meaningless, of metaphysics and pseudosciences from the unified system of the human knowledge (science) and (2) atomistic verificationism, the view that theoretical statements, taken individually, draw their meaning from their relation of semantic identity to special foundational statements, called 'physical control formulas,' the truth of which, individually, is taken to be directly verifiable by observation. Note that, although atomistic verificationists (and many contemporary commentators) use terms like 'synonymy' to characterize the type of semantic relation posited and 'translation' to characterize the operation carried on to establish the semantic relation, neither terms should be confused with its homonym in ordinary language. Rather, the relation of semantic identity posited by atomistic verificationists is akin to the relations of definition in mathematics or of compilation in computer science (both are relations between elements in formal languages).

Anyone who holds these two views, and believes in the value of psychology as a science will strive to show that psychological statements, as theoretical statements, are semantically identical to physical control formulas: physiological and behavioral statements. Hence, Hempel claimed that 'Paul has a toothache' was semantically identical to 'Paul weeps and makes gestures of such and such kinds'; "At the question 'What is the matter?' Paul utters the words 'I have a toothache'"; and so on (Hempel, 1949: 17).

Just as cognitive science was in part developed as a reaction to the limits of psychological behaviorism, in particular Skinner's EAB, much of the original philosophical background underlying cognitive science

was developed through a thorough reflection on the limits of philosophical behaviorism. Indeed, three broad philosophical views on the mind emerged from a reflection on the limits of reductionist philosophical behaviorism: nonreductionist philosophical behaviorism, eliminativist behaviorism, and functionalism. This article addresses the first two (*see Functional Theories of Language* for the third).

Nonreductive Philosophical Behaviorism

Whereas neopositivists aimed to show that mentalist psychology could be a part of the unified system of science, ordinary language philosophers wanted to understand the day-to-day use of language, including mentalistic language (language that contains mental statements and thus can be used to make mental attributions). First, ordinary language philosophers observed that mental attributions are, first and foremost, a mundane practice and that mentalist language may be ill suited to a scientific endeavor such as psychology. Simply assuming that mental statements were well suited for scientific work because of their value in ordinary human practices was deemed to be a category mistake (Ryle, 1949), or as Wittgenstein put it, to misconstrue the logical grammar of language (Wittgenstein, 1953).

The main error thus made was to assume that mental statements ascribe ‘states,’ presumably mental ones, but the criticism extended to other types of states (neurological, functional) of individuals. Instead, mental statements attribute complex behavioral dispositions or behavioral patterns to individuals. Such patterns are taken to be so complex that mental statements cannot in practice be reduced to them. Thus, according to nonreductive philosophical behaviorists, when we attribute a mental state to someone, we are not ascribing a given internal state to that person, but are using shorthand to describe what the person might do in various circumstances.

Ordinary language philosophers based their opposition to the brand of philosophical behaviorism developed by neopositivists on two related problems they saw with reductionist philosophical behaviorism. The first was that reductionist philosophical behaviorists conflated two distinct notions under the heading ‘behavior’: sometimes, the term referred to movements (of the body), and sometimes it referred to actions (of the person who has that body). Although movement statements can be properly viewed as physical control formulas, action statements cannot. The reason why action statements cannot be viewed as physical control formulas pointed to the second problem that philosophical behaviorists saw with reductionist philosophical behaviorism: the

intentional circle (Geach, 1957). The intentional circle refers to the fact that a given mental statement is semantically identical to a given action statement (or set thereof) only on the condition that the person the mental state is attributed to also holds other mental states, and that, to attribute those, one would use mental statements themselves semantically identical to actions only on the condition that the person holds other mental states; and so on, indefinitely. Psychological theoretical statements are thus shown to be irreducible to physical control formulas. The intentional circle argument is a particular instance of a more general argument that applies to any attempt to use semantic identity to justify the reduction of theoretical statements individually to physical control formulas. Let us turn to that more general argument.

Eliminative Philosophical Behaviorism

Atomistic verificationism is at the heart of the neopositivist conception of science, including its reductive philosophical behaviorism. The intentional circle argument brings into question the idea that psychological theoretical statements can be translated solely into physical control formulas – that is, without referring back to other psychological theoretical statements. It is as if all statements, theoretical and observational, are a connection in a kind of network. Drawing on Pierre Duhem’s confirmation holism, Quine broadened the scope of the intentional circle argument to cover all of the sciences: confirmational circularity between theoretical and observational statements becomes the norm rather than psychology’s exception. Holding on to verificationism, which ties meaning to observational confirmation, Quine rejected atomistic verificationism in favor of holistic verificationism. Behaviorism in psychology thus stops being a peculiarity in the sciences, owing to the quirky nature of its theoretical statements, but equal in that regard to theories in other sciences.

Having thus broadened the ordinary language philosopher’s argument against reductive philosophical behaviorism, Quine could have opted for their nonreductive behaviorism. However, he supplied his argument against reductive behaviorism with an argument against all intensional language in science; that is, all language in which extensional inference principles, such as existential generalization and the intersubstitutability of identicals, fail. Nevertheless, Quine’s position was quite similar to that of the nonreductive behaviorists. They both rejected reductive behaviorism and mentalist scientific psychology: Quine, because of his rejection of intensional language generally, and ordinary language philosophers

because they viewed with suspicion any extension of ordinary linguistic practices to science.

The Return of Psychological Behaviorism?

Most accounts of psychological behaviorism end with Chomsky's successful attack on Skinnerian behaviorism, and most accounts of philosophical behaviorism end with Quine's broad attack on neo-positivist reductive physicalism, forgetting that he replaced reductive behaviorism with a more radical eliminative behaviorism. However, since most linguists and psychologists did not follow in Quine's eliminative footsteps, opting instead for the then-growing paradigm of cognitive science, which promised a science of intentionality, a modern student of psychology and linguistics may thus be led to believe that behaviorism is long dead and buried.

However, various elements of behaviorist thinking are making a comeback. Eric Kandel won the Nobel Prize in Medicine in 2000 for his discovery of the molecular basis of three related forms of learning: sensitization, habituation, and classical conditioning (see Kandel *et al.*, 2000). In addition, many neural modelers are now replacing back-propagation in their connectionist models of cognitive capacities with reinforcement learning algorithms, inspired by Skinnerian learning mechanisms. Those algorithms have certain computational advantages over back-propagation that make them more suitable for learning in complex systems, and they are thought to be much more biologically plausible than back-propagation. Moreover, the physiological mechanisms of reinforcement learning are currently being worked out and are thought to involve dopamine and dopaminergic systems as reward systems. Finally, a new trend in robotics, suggestively called Behavior-Based Robotics, shuns central representations and computational systems in favor of simple behaviors strategically connected in a subsumption architecture (Brooks, 1999).

The two questions to ask, a half-century after the initial rejection of behaviorism by cognitive science, is not whether behaviorism is false (it is) but (1) to what extent does our intelligence rely on reflex-like input-output or a modular mechanism, and (2) to what extent is our cognitive life shaped by the type of learning mechanisms studied by behaviorists?

Boole and Algebraic Semantics

E L Keenan, University of California, Los Angeles, CA, USA

A Szabolcsi, New York University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

In 1854 George Boole, a largely self-educated British mathematician, published a remarkable book, *The laws of thought*, in which he presented an algebraic formulation of “those operations of the mind by which reasoning is performed” (Bell, 1965: 1). Since then, boolean algebra has become a rich subbranch of mathematics (Koppelberg, 1989), with extensive applications in computer science and, to a lesser extent, linguistics (Keenan and Faltz, 1985). Here we illustrate the core boolean notions currently used in the study of natural language semantics. Most such applications postdate Boole’s work by more than a century, though Boole (1952: 59) anticipated some of the linguistic observations, pointing out, for example, that *Animals are either rational or irrational* does not mean the same as *Either animals are rational or animals are irrational*; similarly, *Men are, if wise, then temperate* does not mean *If all men are wise then all men are temperate*. Generative grammarians rediscovered such truths in the latter third of the 20th century.

We begin with the basic notion of a *partially ordered set* (poset) and characterize richer structures with linguistic applications as posets satisfying additional conditions (Szabolcsi, 1997; Landman, 1991).

A poset consists of a domain D of objects on which is defined a binary relation R , called a *partial order* relation, which is *reflexive* (for all x in D , xRx), *transitive* (xRy and yRz implies xRz), and *antisymmetric* (xRy and yRx implies $x = y$). For example, the ordinary arithmetical \leq relation is a partial order: $n \leq n$, any natural number n ; if $n \leq m$ and $m \leq p$, then $n \leq p$; and if $n \leq m$ and $m \leq n$, then $n = m$. Similarly, the subset relation \subseteq is reflexive: any set A is a subset of itself. And if $A \subseteq B$ and $B \subseteq C$, then $A \subseteq C$, so \subseteq is transitive. And finally, if $A \subseteq B$ and $B \subseteq A$, then $A = B$, that is, A and B are the same set, since they have the same members. So partial order relations are quite familiar from elementary mathematics.

A case of interest to us is the arithmetical \leq restricted to $\{0, 1\}$. Here $0 \leq 1$, $0 \leq 0$ and $1 \leq 1$, but 1 is not ≤ 0 . Representing the truth value ‘False’ as 0 and ‘True’ as 1, we can say that a conditional sentence ‘if P then Q ’ is True if and only if $TV(P) \leq TV(Q)$, where $TV(P)$ is the truth value of P , etc. Thus we think of sentences of the True/False sort as denoting in a set $\{0, 1\}$ on

which is defined a partial order, \leq . The denotations of expressions in other categories defined in terms of $\{0, 1\}$ inherit this order. For example, one-place predicates ($P1$ s), such as *is even* or *lives in Brooklyn*, can be presented as properties of the elements of the set E of objects under discussion. Such a property p looks at each entity x in E and says ‘True’ or ‘False’ depending on whether x has p or not. So we represent properties p, q as functions from E into $\{0, 1\}$, and we define $p \leq q$ if and only if (iff) for all x in E , $p(x) \leq q(x)$, which just means if p is True of x , then so is q . The \leq relation just defined on functions (from E into $\{0, 1\}$) is provably a partial order.

Other expressions similarly find their denotations in a set with a natural partial order (often denoted with a symbol like ‘ \leq ’). A crucial example for linguists concerns the denotations of count NPs (Noun Phrases), such as *some poets*, *most poets*, etc., as they occur in sentences (S s) like *Some poets daydream*. We interpret this S as True iff there is an entity x that both the ‘poet’ property p and the ‘daydreams’ property d map to 1. Similarly, *No poets daydream* is True iff there is no such x . And *Most poets daydream* is True iff the set of x such that $p(x)$ and $d(x) = 1$ outnumbers the set such that $p(x) = 1$ and $d(x) = 0$. That is, the set of poets that daydream is larger than the set that don’t. And for E, G possible NP denotations (called *generalized quantifiers*), we define $F \leq G$ iff for all properties p , $F(p) \leq G(p)$. This relation is again a partial order.

As NP denotations map one poset (properties) to another (truth values), it makes sense to ask whether a given function F *preserves* the order (if $p \leq q$, then $F(p) \leq F(q)$), *reverses* it (if $p \leq q$, then $F(q) \leq F(p)$), or does neither. *Some/all/most poets* preserve the order, since, for example, *is laughing loudly* \leq *is laughing* and *Some poet is laughing loudly* \leq *Some poet is laughing*, which just means, recall, that if the first sentence is True, then the second is. In contrast, *no poet* reverses the order, since, in the same conditions, *No poet is laughing* implies *No poet is laughing loudly*. The reader can verify that *fewer than five poets*, *neither poet*, *at most six poets*, and *neither John nor Bill* are all order reversing. And here is an unexpected linguistic correlation: reversing order correlates well with those subject NPs that license negative-polarity items, such as *ever*:

- (1a) No student here has ever been to Pinsk.
- (1b) *Some student here has ever been to Pinsk.

Observe that as a second linguistic application, modifying adjectives combine with property-denoting expressions (nouns) to form property-denoting

expressions and can be represented semantically by functions f from properties to properties. For example, *tall* combines with *student* to form *tall student*, and semantically it maps the property of being a student to that of being a tall student. And overwhelmingly when f is an adjective function and p a property, $f(p) \leq p$. All tall students are students, etc.

In fact, the denotation sets for the expressions we have discussed possess a structure much richer than a mere partial order: they are (boolean) lattices. A *lattice* is a poset in which for all elements x, y of the domain, the set $\{x, y\}$ has a *least upper bound* (lub) noted $(x \vee y)$ and read as ‘ x join y ,’ and a *greatest lower bound* (glb), noted $(x \wedge y)$ and read as ‘ x meet y .’ An *upper bound* (ub) for a subset K of a poset is an element z that every element of K is \leq to. An ub z for K is a lub for K iff $z \leq$ every ub for K . Dually a *lower bound* (lb) for K is an element $w \leq$ every element of K ; such a w is a glb for K iff every lb for K is $\leq w$. For example, in the truth value lattice $\{0,1\}$, lubs are given by the standard truth table for disjunction: $1 \vee 1 = 1$, $1 \vee 0 = 1$, $0 \vee 1 = 1$, and $0 \vee 0 = 0$. That is, a disjunction of two false Ss is False, but True otherwise. Similarly, glbs are given by the truth table for conjunction: a conjunction of Ss is True iff each conjunct is, and False otherwise. So here the denotation of *or* is given by \vee , and that for *and* by \wedge . And this is quite generally the case. In our lattices of functions, for example, $f \vee g$, the lub of $\{f, g\}$, is that function mapping each argument x to $f(x) \vee g(x)$. Similarly, $f \wedge g$ maps each x to $f(x) \wedge g(x)$. So, for example, in the lattice of properties, the glb of $\{\text{POET}, \text{DOCTOR}\}$ is that property which an entity x has iff $\text{POET}(x) = 1$ and $\text{DOCTOR}(x) = 1$, that is, x is both a poet and a doctor. So, in general, we see that the lattice structure provides denotations for the operations of conjunction and a disjunction, regardless of the category of expression we are combining. We might emphasize that the kinds of objects denoted by Ss, P1s, Adjectives, NPs, etc., are quite different, but in each category conjunctions and disjunctions are generally interpreted by glbs and lubs of the conjuncts and disjuncts. So Boole’s original intuition that these operations represent properties of mind – how we look at things – rather than properties specific to any one of these categories, is supported.

And we are not done: boolean lattices present an additional operation, *complement*, which provides a denotation for negation. Note that negation does combine with expressions in a variety of categories: with Adjectives in *a bright but not very diligent student*, with P1s in *Most of the students drink but don’t smoke*, etc. Formally, a lattice is said to be *bounded* if its domain has a glb (noted 0) and a lub (noted 1). Such a lattice is *complemented* if for every x there is a y such

that $x \wedge y = 0$ and $x \vee y = 1$. If for each x there is exactly one such y , it is noted $\neg x$ and called the *complement* of x . In $\{0, 1\}$, for example, $\neg 0 = 1$ and $\neg 1 = 0$. In our function lattices, $\neg f$ is that function mapping each x to $\neg(f(x))$. In distributive lattices (ones satisfying $x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$ and $x \vee (y \wedge z) = (x \vee y) \wedge (x \vee z)$), each x has a unique complement. A lattice is called *boolean* if it is a complemented distributive lattice. And, again, a linguistic generalization: the negation of an expression d in general denotes the complement of the denotation of d .

Given uniqueness of complements, \neg is a function from the lattice to itself, one that reverses the order: if $x \leq y$, then $\neg y \leq \neg x$. We expect, correctly then, that negation licenses negative-polarity items in the predicate, and it does: *He hasn’t ever been to Pinsk* is natural, **He has ever been to Pinsk* is not. Reversing the order on denotations, then, is what ordinary negation has in common with NPs such as *no poet*, *neither John nor Bill*, etc., which as we saw earlier also license negative-polarity items.

The boolean lattices we have so far invoked have further common properties. They are, for example, *complete*, meaning that each subset, not just ones of the form $\{x, y\}$, has a glb and a lub. They are also atomic (Keenan and Faltz, 1985: 56). In addition, different categories have some distinctive properties – which, with one exception, space limitations prevent us from reviewing (see also Keenan, 1983). The exception is the lattice of count NP denotations, needed for expressions such as *most poets* and *five of John’s students*. This lattice has the property of having a set of complete, independent (free) generators, called *individuals* (denotable by definite singular NPs, such as *John*, *Mary*, *this poet*). This means that any function from properties to truth values is in fact a boolean function (meet, join, complement) of individuals (Keenan and Faltz, 1985: 92). And this implies that the truth value of an S of the form $[[\text{Det N}] + \text{P1}]$, for P1 noncollective, is booleanly computable if we know which individuals have the N and the P1 properties. The truth of Ss like *Most of the students laughed*, *No students laughed*, etc., is determined once that information is given. This semantic reduction to individuals is a major simplification, in that the number of individuals is the number of elements in E , whereas the number of possible NP denotations is that of the power set of the power set of E . So speaking of an E with just four elements, we find there are just four individuals but 65 536 NP denotations.

These freely generated algebras show up in another, unexpected syntactic way. Szabolcsi and Zwarts (1993) observed that negation determines a context that limits the class of questions (relative clauses, etc.) we can grammatically form. Thus, the questions

in (2) are natural, but those in (3), in which the predicates are negated, are not:

- (2) How tall is John? How much did the car cost?
 (3) *How tall isn't John? *How much didn't the car cost?

It is tempting to say simply that we cannot question out of negative contexts, but that is not correct. Both questions in (4) are acceptable:

- (4) How many of the books on the list did/didn't you read?

A more accurate statement is that negation blocks questioning from domains that lack individuals (free generators), such as amounts and degrees. So, as with the distribution of negative-polarity items, we find an unexpected grammatical sensitivity to boolean structure.

Much ongoing work in algebraic semantics focuses on NPs (and their predicates) that are not boolean compounds of individuals. The predicates in the Ss in (5) force us to interpret their subjects as *groups*.

- (5a) John and Mary respect each other/are a nice couple.
 (5b) Russell and Whitehead wrote *Principia mathematica* together.
 (5c) The students gathered in the courtyard/surrounded the building.
 (5d) Six teaching assistants graded 120 papers between them.

Respecting each other (*being a nice couple*, etc.) holds of a group of individuals if certain conditions among them obtain. But it does not make sense to say **John respects each other* (**He is a nice couple*, etc.), so we must interpret *and* somewhat differently from the glb operator discussed earlier. We note that the other boolean connectives – such as *either ... or ...* and *neither ... nor ...* – do not admit of a reinterpretation in the way that *and* does (Winter, 2001). **Either John or Mary respect each other* is nonsense: the disjunctive subject still forces a lub interpretation in which *respect each other* would hold of at least one of the disjuncts.

First attempts to provide denotations for the subject NPs in (5) involve enriching the understood domain E of entities with a partial order relation called *part-of*, to capture the sense in which the individual John is part of the denotation of *John and Mary* in (5a) or some individual student is part of the group of students in (5c), etc. The group itself is a new type of object, one that is the lub of its parts. And new types of predicates, such as those in (5), can select these new objects as arguments. Thus, the domain of a model is no longer a mere set E but is a *join semi-lattice*, a set equipped with a *part-of* partial order in which each

nonempty subset has a lub (see Link, 1983, 1998; Landman, 1991).

Yet other new types of arguments are *mass terms* (6a) and *event nominals* (6b).

- (6a) Water and alcohol don't mix.
 (6b) 4000 ships passed through the lock last year.
 (Krifka, 1991)

Mass term denotations have a natural *part-of* relation: if I pour a cup of coffee from a full pot, the coffee that remains, as well as that in my cup, is part of the original coffee. So mass term denotations are in some way *ontologically uniform*, with the result that definitional properties of a whole also apply to their parts – the coffee I poured and the coffee that remains are both coffee. This contrasts with predicates in (5), where *respect each other*, *gather in the courtyard*, etc., do not make sense even when applied to the proper parts of their arguments. In general, mass terms are much less well understood than count terms (see Pelletier and Schubert, 1989; Link, 1998).

Last, observe that (6b) is ambiguous. It has a count reading, on which there are 4000 ships each of which passed through the lock (at least once) last year. But it also has an event reading, of interest here, on which it means that there were 4000 events of ships passing through the lock. If, for example, each ship in our fleet of 2000 did so twice, then there were 4000 passings but only 2000 ships that passed.

Now, the event in (6b) has the individual passing events as parts, so such complex events exhibit something of the ontological uniformity of mass terms. But there are limits. The subevents of a single passing (throwing lines to the tugboats, etc.) are not themselves passings. So events present a *part-of* partial order with limited uniformity, and at least some events can be represented as the lubs of their parts. But in distinction to pure mass terms, events are ontologically complex, requiring time and place coordinates, Agent and Patient participants, etc., resulting in a considerable enrichment of our naïve ontology (see Parsons, 1990; Schein, 1993; and Landman, 2000).

Causal Theories of Reference and Meaning

ismuch more important on the causal approach to reference, as compared with the causal approach to meaning.)

Reference, Meaning, and Causal Theories

The theory of reference and the theory of meaning are two closely related, fundamental strains within the study of mind and language. The aim of a theory of meaning is to explain what it is that competent speakers of a given language know, or are able to do, in virtue of which they are able to use the language to communicate. The aim of the theory of reference is to explain what it is in virtue of which words refer to what they do, how it is that utterances can hook onto and express information about particular things.

The exact relation between meaning and reference is a controversial matter (in large part because of the wide variety of theoretical approaches to meaning). According to some views, the meaning of an expression is precisely its referent, and so theories of meaning and of reference are just slightly different roads in to what is essentially the same task. Opponents of this notion point to co-referential expressions that differ in meaning (such as 'Portugal' and 'the country immediately west of Spain'), or to meaningful expressions that do not seem to refer to anything ('of', or 'for the sake of'), to show that meaning is distinct from reference. Or again, many theorists hold that proper names refer but cannot really be said to have a meaning, or that complete sentences have a determinate meaning but do not refer to anything.

In any case, the causal theory of reference (i.e., words refer to what they do by virtue of a certain sort of causal relation between word and referent) and the causal theory of meaning (i.e., words mean what they do by virtue of a certain sort of causal relation between word and meaning) are, historically and conceptually, distinct views. To help avoid confusion, I will distinguish the relevant approach to reference by calling it 'the causal-historical theory.' ('Historical' is an appropriate distinguishing mark because the history of how a word is transmitted from its original inception to the current speaker

The Causal-Historical Theory of Reference

The causal-historical theory of reference was developed in the 1960s and 1970s. It is explicitly developed only for proper names (cf. Donnellan, 1970; Kripke, 1972) and natural kind terms (cf. Kripke, 1972; Putnam, 1975). However, Kaplan (1977) raises some related points about indexical expressions, and there have been attempts to fashion a fully general approach to reference along these lines (for discussion, see Stalnaker, 1997; Devitt and Sterenly, 1999). The theory has replaced the descriptivist approach to reference, different versions of which were defended by Frege and Russell, as the orthodox approach to reference. (see **Proper Names: Philosophical Aspects** for discussion.)

According to the causal-historical theorists, descriptivists are wrong to demand that, in order to significantly use a term, speakers need to have a uniquely identifying description of its referent. Rather, once a convention is in place, linking a term to its referent, a deferential intention to comply with this practice – i.e., to use 'X' to refer to what others have used 'X' to refer to – is all that is required in order to use the term to refer. The view has it that certain expressions refer to certain things in virtue of a causal-historical relation between word and object, initially fixed during a dubbing or baptism and propagated from there to subsequent speakers, who implicitly defer to that initial dubbing in using the expression to refer.

The notion of a causal-historical chain as that which is criterial in determining reference is developed more or less independently by Donnellan and Kripke. Donnellan (1970: 277) concludes an argument against descriptivism with the claim that "... in some way the referent must be historically, or, we might say, causally connected to the speech act." Donnellan (1974: 17) articulates the point at a bit

more length: “Suppose someone says ‘Socrates was snub-nosed’, and we ask to whom he is referring. ... [T]his calls for a historical explanation; we search not for an individual who might best fit the speaker’s descriptions ... but rather for an individual historically *related* to his use of the name.” Kripke (1972: 94–95) uses similar terms to describe his approach: “... It’s in virtue of our connection with other speakers in the community, going back to the referent himself, that we refer to a certain man ... In general, our reference depends not just on what we think ourselves, but on other people in the community, the history of how the name reached one, and things like that. It is by following such a history that one gets to the reference.” And again Kripke (1972: 106): “... reference actually seems to be determined by the fact that the speaker is a member of a community of speakers who use the name. The name has been passed to him by tradition from link to link.”

The causal-historical theory is an externalist approach to reference, in that reference depends largely on factors external to the speaker’s head – factors pertaining to the speaker’s linguistic community and to the environment in which the expression in question evolved. (Descriptivists tend to be internalists, insofar as they hold that reference is fully determined by the speaker’s beliefs and discriminative abilities.) On the causal-historical view, the criteria for the correct application of a word are not, in general, introspectively accessible to competent speakers; one can competently use ‘gold’ or ‘Aristotle’ without knowing anything that would distinguish Aristotle from Plato, or gold from fool’s gold. Mistaken or ignorant speakers can still single out specific referents via these complex, communal, causal-historical mechanisms. (see **Externalism about Content** for more on this.)

Contra the descriptivists, the causal-historical theorists argue that the meaning of a proper name is not some kind of descriptive sense (see **Direct Reference; Proper Names: Philosophical Aspects; Reference: Philosophical Theories** for discussion). From here, the conclusion that the semantic contribution of a name is just its referent looks compelling. This is why the theory has led to a resurgence of interest in the Millian view of proper names (i.e., the meaning of a name is just its referent) and in the Russellian approach to singular propositions (i.e., the proposition expressed by a sentence containing a name – say, ‘Kaplan is in California’ – is individuated solely in terms of the individual and property that it is about, as opposed to being individuated in terms of more finely-grained concepts or meanings). Many think that the causal-historical chain of transmission story

about how a word refers to something in particular nicely complements, and fleshes out, these doctrines of Mill and Russell.

The causal-historical theory does not aim to give a reductive analysis of reference. For example, Kripke (1972: 96) says: “When the name is ‘passed from link to link,’ the receiver of the name must, I think, intend to use it with the same reference as the man from whom he heard it ... [T]he preceding account hardly *eliminates* the notion of reference; on the contrary, it takes the notion of intending to use the same reference as a given.” (Cf. Kaplan’s [1990] discussion of the point that the intention to preserve reference is not itself a causal notion.) Thus, those who seek to naturalize reference, by reducing the relation of reference to something more scientifically respectable, must either significantly alter the causal-historical view, or look elsewhere.

The Causal Theory of Meaning

In contrast, the causal theory of meaning (also called the ‘information-theoretic’ approach to meaning) is explicitly in the business of explaining semantic phenomena in non-semantic terms. The general aim here is a naturalistic account of the phenomenon of meaning, and the thought is that the notion of causation is the most promising place from which to start. Dretske (1981) is a seminal proponent of this approach, and Fodor (1987, 1990) develops related accounts. Stampe (1977), another influential proponent, gives the following programmatic sketch: “We have causal theories ... of knowledge and memory, of belief, of evidence, of proper and common names, and of reference. If ... these phenomena should turn out to have causal analyses, it will be no mere coincidence. Only their having something in common would make it so ... [The root of this convergence] is that *representation* is essentially a causal phenomenon” (1977: 81).

The general idea behind the causal theory of meaning is that linguistic meaning is a species of causal co-variance. Roughly, the goal is to show that ‘means’ means (more or less) the same thing in (1) and (2), that both cases are, at root, cases of reliable correlation:

1. Smoke means fire.
2. ‘Fire’ means fire.

For a word to mean something in particular is for the word to reliably indicate that thing. Alternatively, a word ‘W’ means M if M tends to cause or bring about tokens of ‘W.’ (The account is intended to apply not only to tokens of ‘W’ that are actually uttered, but also, and more fundamentally, to occurrences of the word in thought.)

If a satisfactory account of meaning were forthcoming down this avenue, this would be a monumental leap forward for the human and cognitive sciences. As yet, there is nothing remotely resembling a satisfactory scientific treatment of meaning; given the fundamental and pervasive roles that meaningful thoughts and utterances play in our lives, that is a rather large gap in our scientific understanding of human beings.

(Note that Grice [1957] criticizes a view that he calls ‘the causal theory of meaning’ – the core of which is the idea that the meaning of an expression ‘E’ is (roughly) the content of the attitude that is prone to cause a speaker to utter ‘E,’ and that hearing ‘E’ is prone to cause in listeners. This view has not played a major role in the philosophy of language; but nonetheless some of Grice’s arguments against it are echoed in the criticisms, described in the next section, of the above information-theoretic causal theory.)

Problems and Prospects

There are many problems with the causal-historical theory of reference (which are discussed at more length in **Reference: Philosophical Theories**). Evans (1973) and Searle (1983) develop counterexamples to the theory, cases where it seems to be committed to unwelcome consequences. Furthermore, many of the semantic views with which the theory has been allied (such as those of Mill and Russell mentioned earlier in the second section of this article) are controversial (*see Direct Reference; Proper Names: Philosophical Aspects* for discussion). More generally, the causal-historical view is just a sketchy picture – it does not offer anything like specific necessary or sufficient causal-historical conditions for identifying the referent of an utterance or inscription. Any utterance stands in an awful lot of causal relations to an indefinite range of things; to single out precisely which subset of these ubiquitous causal relations are semantically relevant – let alone precisely which of them are relevant to determining the referent of a particular use of a particular expression – is a daunting task that is as yet barely begun.

The situation is worse for the (more reductionist, and so more ambitious) causal theory of meaning. It not only falls prey to the problems that befalls the causal-historical approach to reference but also gives rise to some distinctive problems of its own. Basically, for almost any word-meaning pair ‘W’-M, it is not difficult to come up with conditions in which things distinct from M tend to cause ‘W’s, and conditions in which M does not tend to cause ‘W’s. For instance, in various sorts of suboptimal conditions, cows might tend to cause tokens of ‘horse,’ but

nonetheless – regardless of how dark it is (or how far away they are, what they are disguised as, etc.) – these cows are distinct from the meaning of ‘horse.’ In the other direction, if a horse was to ‘baa’ like a sheep, or was painted with zebra-stripes, or what have you, these misleading factors would affect its tendency to cause ‘horse’-tokens, but would not have the slightest effect on the fact that the term ‘horse’ correctly applies to it. In short, causation is a much more indiscriminating relation than meaning; and this is the source of all manner of problems for the project of using causation to build an account of meaning.

There are many refinements of the basic causal-theoretic view, intended to skirt these elementary problems and their many variants. However, the consensus seems to be that this type of causal theory can only succeed in delivering an account of meaning that accommodates our intuitions about the normativity and determinacy of meaning (i.e., respectively, it is possible to misapply a term, and the terms ‘A’ and ‘B’ can differ in meaning even if all As are Bs) if it smuggles in semantic notions, and thus helps itself to meaning, as opposed to offering an account of meaning (for discussion, see Loewer, 1997).

To sum up: the causal theory of reference is the view that a word refers to that to which it stands in the right sort of causal-historical relation. Since the 1970s, it has become the orthodox approach to reference. However, many problems remain to be worked out, for this general picture to yield a satisfactory, comprehensive account of reference. The causal theory of meaning is the view that the meaning of a word is that which reliably causes tokens of the word to be thought or uttered. Many take this to be the most promising avenue for a naturalistic account of meaning. However, there are reasons to think that the approach is too crude to yield an adequate account of linguistic meaning. At best, there are counterexamples that have yet to be satisfactorily addressed.

Character versus Content

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

David Kaplan introduced the content/character distinction in his monograph *Demonstratives* (1989a) to distinguish between two aspects of the meaning of (1) indexical and demonstrative pronouns (e.g., 'I', 'here', 'now', 'this', and 'that') and (2) sentences containing them. Roughly, the content of an occurrence of an indexical or demonstrative is the individual to which it refers, and its character is the rule that determines its referent as a function of context. Thus, an indexical has different contents in different contexts, but its character is the same in all contexts. For instance, the character of 'I' is the rule, or function, that maps a context of utterance to the speaker of that context. This function determines that the content of Sally's utterance of 'I' is Sally.

Content/Character Distinction and Semantics

Sentences containing indexicals or demonstratives are context-dependent in two ways. First, contexts help to determine what these sentences say. Second, contexts determine whether what is said is true or false. For instance, suppose Sally says, 'I'm cold now' at time t . The context supplies Sally as the referent for 'I' and time t as the referent for 'now,' so it helps to determine what Sally said. Other facts about the context, specifically whether Sally is cold at time t , determine whether she said something true or false. Different contexts can play these different roles, as they do when we ask whether what Sally said in one

context would be true in a slightly different context. A central virtue of Kaplan's semantics is that it distinguishes between these two roles of context. For Kaplan, a *context of use* plays the first role, of supplying contents for indexical expressions, and a *circumstance of evaluation* plays the second. A context of use is just a context in which an indexical expression may be used, and which supplies a content for the indexical expression. A circumstance of evaluation is an actual or merely possible situation in which the content of an utterance is evaluated for truth or falsehood.

A semantic framework like Kaplan's, which captures the double-dependence of meaning on context, is sometimes called a two-dimensional semantics. In the two-dimensional framework, a meaningful entity such as a linguistic expression or an utterance determines not a single semantic value but a two-dimensional matrix of semantic values. **Figure 1** represents Kaplan's semantics in this way. In **Figure 1**, the vertical axis of the matrix displays contexts of use (u^1 – u^3) and the horizontal axis displays circumstances of evaluation (c^1 – c^3). Each cell in the matrix gives the extension of the linguistic expression e as used in the specified context of use and evaluated in the specified circumstance of evaluation. In this matrix, the cell in row n and column m gives the

e	c^1	c^2	c^3
u^1	T	F	T
u^2	F	F	F
u^3	T	T	T

Figure 1 Two-dimensional matrix.

semantic value of e in the context of use specified at the beginning of row n and evaluated in the circumstance of evaluation specified at the top of column m . If e is a sentence, cells will be filled in with truth values as illustrated.

Kaplan offers a syntax and semantics for a formal language containing indexicals, demonstratives, and a variety of modal operators. In this formal system, a context of use is an ordered n -tuple of contextual features to which indexicals or demonstratives are sensitive, such as the speaker, time, world, and location of the context. A circumstance of evaluation is an ordered n -tuple of a possible world-state or world-history, a time, and perhaps other elements as would be required given the sentential operators in the language. For Kaplan, all contexts of use are *proper*, which means that the speaker of the context must be located at the time, place, and world of the context. Circumstances of evaluation, however, need not be proper.

Contexts of use and circumstances of evaluation play a role in the specification of the character and content of an expression. The character of any linguistic expression e is a function from contexts of use to contents appropriate for e , i.e., an individual if e is a singular term, a proposition if e is a sentence, and sets of n -tuples of individuals if e is an n -place predicate. Indexical expressions only have contents relative to a context of use. So Kaplan speaks of the content of an occurrence of an expression rather than the content of the expression itself. Contents are evaluated in circumstances of evaluation, and these evaluations yield extensions appropriate to the kind of content under evaluation. So we also can characterize the content of an occurrence of e as a function from circumstances of evaluation to extensions of a type appropriate to e . For instance, the extensions for sentences are truth values, for indexicals, individuals, and for n -place predicates, n -tuples of individuals. For individuals and n -place predicates, these will be constant functions (i.e. the function delivers the same extension in every circumstance of evaluation). It is often simpler to think of contents as individuals (for singular terms), propositions (for sentences) and sets of n -tuples of individuals (for n -place predicates), and Kaplan typically talks about contents in this way. Both ways of thinking of contents are semantically equivalent.

For Kaplan, indexicals and demonstratives are both directly referential and rigidly designating. They are directly referential because they contribute only their referents to the propositions expressed by sentences containing them. They are rigidly designating because, once they secure a content in a context of use, they retain that content in every circumstance of evaluation. Indexicals and demonstratives contrast

with the typical definite description in both respects. Definite descriptions typically contribute a descriptive condition to a proposition rather than an individual, and this descriptive condition is typically satisfied by different individuals in different worlds of evaluation. Although Kaplan's view that demonstratives are directly referential is widely accepted, some recent discussions of complex demonstratives (i.e. expressions of the form 'that F ') have defended a quantificational approach, and some considerations in favor of such an approach may apply to the pure demonstratives 'this' and 'that' (King, 2001).

Kaplan's semantics has technical virtues lacking in earlier treatments of natural language indexicality. It shares with other double-indexing accounts (Kamp, 1971) a technical superiority to single-index theories, which evaluate sentences relative to a single index, which is an ordered n -tuple of features of a context, such as a speaker, time, location, and world. Such theories cannot account for the interaction of indexicals and certain sentence operators. To evaluate the sentence (1), for instance, we need to consider the truth value of the constituent sentence, 'the man who is now President of the United States no longer hold[s] that office' in situations occurring *after* the sentence is uttered.

- (1) Someday, the man who is now President of the United States will no longer hold that office.

But the indexical 'now' in that constituent sentence must still refer to the time (1) is used, and not the time at which the constituent sentence is evaluated. As Hans Kamp has argued, only a double-indexing theory will correctly predict the truth conditions for (1) (Kamp, 1971).

Content/Character Distinction and Philosophy

The content/character distinction sheds light on some specifically philosophical issues involving context-sensitivity in thought and language. These applications involve philosophically significant assumptions, and are more controversial than the applications to the semantics of indexicals and demonstratives.

First, content and character play two roles that Gottlob Frege initially envisioned for the meaning, or sense, of a sentence, one semantic and the other more broadly psychological (Frege, 1892). Frege thought that the sense of a sentence should both determine its truth condition and provide the cognitive significance of beliefs expressible with that sentence. Although Frege expected that one entity, the sense, could play both roles, indexical and demonstrative belief undermines this expectation, since it

appears to require two different entities to play the two roles. Different people who have a belief they could express by saying 'I'm cold' will be in the same psychological/functional state. They will all be shivering and trying to get warmer. But because each person who thinks, 'I'm cold' is a constituent of the content of that thought, all of these thoughts will differ in content. The psychological role of an indexical belief appears to be more closely tied to the character of the sentence the thinker would use to express that belief than to the content of the belief. But the content, rather than the character, is more directly relevant to the truth condition of an occurrence of a sentence containing an indexical.

Second, Kaplan has suggested that the content/character distinction helps to explain the relation between the epistemological notions of logical truth and the *a priori*, on the one hand, and the metaphysical notions of necessity and contingency on the other. Other philosophers have put broadly similar applications of the two-dimensional framework into service to the same end (Stalnaker, 1978, cf. Stalnaker, 2004; Chalmers, 1996; Jackson, 1998). As is evident to anyone who understands sentence (2), it cannot be uttered falsely. Therefore, sentence (2) is in a certain sense a logical or *a priori* truth. Yet it does not express a necessary truth, since occurrences of (3) will typically be false.

(2) I am here now.

(3) Necessarily, I am here now.

Kaplan has suggested that we explain the special status of (2) as follows: metaphysically speaking, (2) is contingently true in virtue of its content. But it has its special epistemic status in virtue of its character: the character of (2) requires that it express a truth in every context of use. Other sentences which may express the same content as a particular occurrence of (2), but a different character, such as (4), do not have the same special epistemic status.

(4) GWB is in Washington, DC on June 16, 2004.

Because (4) and some occurrences of (2) share a content but differ in their epistemic status, it is natural to conclude that contents cannot be the bearers of this special epistemic property. Critics of this account of the *a priori* (Soames, 2005) say that the content/character distinction cannot underwrite the general account of *a priori* knowledge that some of its defenders (Chalmers, 1996; Jackson, 1998) have claimed.

Third, some philosophers have used Kaplan's content/character distinction to distinguish narrow content (i.e. content determined by the internal state of the thinker) from wide content (i.e. content determined by the internal state of the thinker and his or

her environment) (Fodor, 1987; see also Chalmers, 1996; Jackson, 1998, for a related application of two-dimensional semantics to these ends). They suggest that narrow content is loosely modeled on Kaplan's characters, and wide content on Kaplan's contents. That characters seem to capture something important about the psychological roles of belief makes them particularly attractive candidates to model the purely internal aspects of thought. Critics of the approach contend that although characters help to characterize internal states of thinkers, they are not themselves determined by such states (Stalnaker, 1989).

Cognitive Science and Philosophy of Language

S Scott, Washington University in St. Louis,
St. Louis, MO, USA

© 2006 Elsevier Ltd. All rights reserved.

Much contemporary philosophy of language can be viewed as a synthesis of three major traditions: ideal language philosophy, ordinary language philosophy, and cognitivism. In the first three-quarters of the 20th century, philosophers in both the ordinary and ideal language traditions sought to solve or dissolve traditional philosophical problems through careful exegesis of the meanings of words and sentences. For ideal language philosophers, the project was to formally describe how words and sentences ought to be interpreted in scientific and philosophical discourse. For ordinary language philosophers, the project was to characterize the conventions underlying the actual use of words and sentences in ordinary speech. Philosophers in both traditions made a number of lasting contributions to the philosophical and scientific study of language, but they were not just studying language for its own sake. Many philosophers in this period considered the philosophy of language to be first philosophy, the foundation on which other philosophical inquiries are built, and they had other philosophical issues in mind when developing their accounts of language (*see Epistemology and Language; Metaphysics, Substitution *Salva Veritate* and the Slingshot Argument*).

As the limitations of the ordinary and ideal language traditions became apparent and their influence began to decline, the cognitivist tradition in the scientific study of language was growing. Cognitivists view the mind as a computational and representational system and bring a wide variety of empirical evidence to bear on their investigations into the structure and processing of linguistic knowledge in the mind. The synthesis of cognitive science and philosophy of language, or as I shall call it, the new philosophy of language, integrates the formalisms of the ideal language tradition with the careful attention to the nuances of use that characterized the ordinary language tradition. But as cognitivists, many contemporary philosophers of language also take results from linguistics into account and share with other cognitive scientists a commitment to producing theories that are consistent with available psychological and neuroscientific evidence. What follows is a very brief account of the three traditions and their synthesis into the new philosophy of language, ending with a review of some recent work on proper names that exemplifies this new synthesis.

The Ideal Language Tradition

Ordinary speech is a rich source of vagueness, ambiguity, puzzles, and paradoxes, most of which go unnoticed by most speakers. This may not matter all that much for the purposes of ordinary conversation, but in scientific and philosophical discourse the imprecision of ordinary language is not to be tolerated. So said Bertrand Russell, Gottlob Frege, W. V. O. Quine, and the philosophers of the ideal language tradition. According to them, ordinary language contains certain deficiencies and the philosopher's job is to provide remedies (Russell, 1919: 172, describes one such "deficiency" as a "disgrace to the human race"). The goal of these philosophers was to standardize and regiment language, explain away puzzles and paradoxes, and formally characterize ambiguities. Their aim was to transform ordinary language into something closer to an ideal language – one that scientists and philosophers could use to express their hypotheses about the world. The strengths and weaknesses of their approach can be illustrated using Russell's theory of proper names.

Example: Proper Names

The idea that scientific hypotheses are about the world was key for the ideal language philosophers. Sentences in science and philosophy, not to mention ordinary conversation, often attribute properties to objects in the real world (*see Objects, Properties, and Functions*). Accordingly, a defining feature of ideal language philosophy was the idea that the relationship of reference is a basic unit of meaning (*see Reference: Philosophical Theories*), and the starting point was the analysis of simple property attribution sentences such as:

- (1a) Venus is round.
- (1b) Venus is a star.

Here are some basic intuitions: Sentence (1a) is true because the planet Venus has the property of being round, and sentence (1b) is false because the planet Venus does not have the property of being a star.

Here is a simple analysis that respects those intuitions: In both sentences, the proper name *Venus* refers to an object (*see Proper Names: Philosophical Aspects*), the remaining words *is round* and *is a star* attribute properties to that object, and the sentences refer to the propositions that Venus is round and that Venus is a star, respectively (*see Propositions*). This analysis is shown more formally in (2), where VENUS denotes the actual object Venus, not a word or an idea.

Simple Analysis of (1)

(2a) *round*(VENUS)

(2b) *star*(VENUS)

This analysis of simple sentences can be developed into a powerful system for characterizing the semantics of much more complex and interesting sentences. But, unfortunately, it also runs into fatal problems with certain sentences that seem just as simple as those in (1). For instance, it is not easy to see how to extend the analysis to cover:

(3) Vulcan is round.

This sentence was once thought to be true by astronomers who postulated the existence of a planet, tentatively named *Vulcan*, to explain the observed perturbations in Mercury's orbit. It is now known that there is no such planet or, to put it another way, that *Vulcan* is an empty name (see **Empty Names**). So, although (3) is clearly meaningful and has a grammatical form that parallels the sentences in (1), the simple analysis will not work in this case. Recall that (1a) is true because the object referred to by the name *Venus* has the property of roundness. But in (3), there is no object named *Vulcan* and therefore nothing to which any such property can be applied.

Here we have the makings of a puzzle – if reference is as basic to meaning as it appears to be, then how is it possible to say meaningful things using words that have no referents? One option is to allow that nonexistent things such as Vulcan, Santa Claus, unicorns, and so on really do have some kind of objecthood. But most philosophers would reject this option because, as Russell (1919: 169) put it, “logic . . . must no more admit a unicorn than zoology can; for logic is concerned with the real world just as truly as zoology.” Another option is to just bite the bullet and accept that (3) does not express a proposition and is therefore meaningless. Although some contemporary philosophers of language have taken this route (e.g., Adams and Stecker, 1994), the ideal language philosophers did not want to take that way out either because to do so would be to render many important scientific and philosophical hypotheses meaningless.

Russell's Theory of Descriptions

Russell found a solution to the problem of empty names (and other philosophical puzzles) in his theory of descriptions (see **Descriptions, Definite and Indefinite: Philosophical Aspects**). Briefly, Russell held that names such as *Vulcan* and *Venus* do not directly refer but instead are shorthand for definite descriptions such as *the planet causing perturbations in*

Mercury's orbit and *the second planet from the sun*, respectively. That is, names are disguised definite descriptions. So, when scientists utter sentences such as those in (1) and (3), what they assert is something more like:

Step One of Russell's Analysis of (1) and (3)

(4a) The second planet from the sun is round.

(4b) The second planet from the sun is a star.

(4c) The planet causing perturbations in Mercury's orbit is round.

On the face of it, it looks like (4c) has the same problem as (3) – descriptions such as *The planet causing perturbations in Mercury's orbit* seem like they should be interpreted as namelike referring expressions. But Russell did not think so. He thought that descriptions such as these should be analyzed as general, quantificational statements about what exists in the world. In the case of (4c), the correct interpretation, according to Russell, is that there is exactly one planet causing perturbations in Mercury's orbit and all such planets are round. This analysis is expressed in quantificational notation in (5), where *pm*() stands for the property of being a planet that causes perturbations in Mercury's orbit. (Some of the inessential details have been simplified in a way that Russell might have objected to, but that does not matter for current purposes.)

Step Two of Russell's Analysis of (3)

(5a) There exists exactly one planet *x* that is the cause of the perturbations in Mercury's orbit, and it is round.

(5b) $\exists x ((\forall y (pm(y) \leftrightarrow y = x)) \ \& \ round(x))$

In this final analysis, there is no longer any element in the proposition corresponding to the name *Vulcan* and no role available for any referent, and thus the puzzle of empty names disappears. To recap: Names are shorthand for disguised definite descriptions, and sentences that contain definite descriptions express general propositions about the world and the things in it rather than singular propositions about particular entities.

Limitations of the Ideal Language Approach

Russell's analysis of proper names, as clever and influential as it is, runs afoul of ordinary intuitions. Sentence (3) seems to have a very simple subject-predicate form, but the proposition in (5) that provides the meaning for (3) bears no resemblance to that form. Furthermore, (5) is false because it asserts the existence of something that does not exist (i.e., it asserts the existence of a planet that causes perturbations in Mercury's orbit, but there is no such planet). But it is not clear to everybody that (3) really is false

(see Strawson, 1950; and the reply by Russell, 1957). To many people, questions such as *Is Vulcan round?* have the same kind of problem as questions such as *Have you stopped cheating on exams yet?* – to answer either “yes” or “no” would be to accept a problematic premise.

Russell was not driven to this analysis of simple sentences as an attempt to characterize how ordinary speech works but as an attempt to dissolve an apparent logico-scientific puzzle that arises when we take the referential commitments of ordinary speech seriously. But the analysis ends up providing no account of the fact that people seem quite capable of making what appear to be true claims about nonexistent things.

- (6a) Santa Claus usually wears a red suit.
- (6b) Pegasus looks a lot like a horse.

Russell’s theory of disguised definite descriptions makes the sentences in (6) come out false, contrary to most people’s intuitions. His theory preserves the apparent meaningfulness of these sentences, and does so without maintaining any problematic commitments to entities such as Pegasus and Santa Claus, but at the price of a theory that may not have much to say about their ordinary use.

The Ordinary Language Tradition

As vague, ambiguous, and rife with semantic puzzles as ordinary language is, it also contains a wealth of information that philosophers cannot afford to ignore. In order to discover anything meaningful about important philosophical topics such as Truth, Knowledge, and Justice, philosophers need to know what *truth*, *knowledge*, *justice*, and other related words actually mean in ordinary language. This was the perspective of Gilbert Ryle, H. P. Grice, J. L. Austin, P. F. Strawson, Ludwig Wittgenstein (in his later works), and the philosophers of the ordinary language tradition. According to them, philosophers must pay careful attention to the nuances of ordinary language use and must be particularly wary of misusing ordinary language expressions in their philosophical theories. In many ways, this tradition was radically opposed to the ideal language tradition: whereas the ideal language project was a prescriptive project, concerned with legislating how language ought to be understood, the ordinary language approach was purely descriptive, concerned with the investigation of how language is actually used; whereas ideal language philosophers sought to construct a theory of meaning based on reference to things in the world, ordinary language philosophers sought to construct a theory of meaning

based on conventions of ordinary use (see *Use Theories of Meaning*). But despite these differences, both traditions shared a common motivation, namely, the analysis of language in order to help solve or dissolve philosophical problems. It is just that in pursuing this common aim, ideal language philosophers were busy constructing a new language while ordinary language philosophers were busy pointing out how philosophers tended to misuse the old one.

Example: Ryle on Free Will

Ordinary language philosophers thought that the meaning of an expression is the conventions governing its use. Thus, to get at the meaning of an expression, we have to examine how it is ordinarily used. The standard technique is to assemble a list of sentences containing a given expression and then try to find conditions under which it would be inappropriate or nonsensical to use those sentences. Whatever those conditions turn out to be, their negation must be part of the meaning of the word in question. (Notice that this makes short work of the puzzle of empty names. Because the meaning of a word is the conventions governing its use, names can have meaning whether they have a referent or not.)

As an example of ordinary language analysis in action, consider Ryle’s (1949) investigation of the word *voluntary*. Ryle noted that philosophers often characterize free will (another important philosophical topic) based on the distinction between voluntary and involuntary actions – free will is said to be involved in an action when it is performed voluntarily and not when it is performed involuntarily. So *voluntary* (along with grammatical variants such as *voluntarily*) is an important word in philosophy, but what does it actually mean in ordinary language? Consider the following sentences:

- (7a) Benazir went to school voluntarily.
- (7b) Hussein ate the sandwich voluntarily.
- (7c) Ahmad watched *Seinfeld* voluntarily.

As Ryle observed, such uses of *voluntary* and its grammatical variants seem odd or wrong in any situation in which there is no reason to believe that the person in question ought not to have performed the action. So if Benazir has been banned from campus or hates school or is supposed to be doing something else, then (7a) might make sense. But if there is no reason to suppose anything like that, then the word *voluntarily* should be left out. Ditto for (7b) and (7c). From these sorts of considerations, Ryle concluded, part of the meaning of the word *voluntary* must include the condition that it can only be used in the description of an action that for some reason ought not to have been performed.

To bring this back to the philosophical problem of free will, Ryle noted that philosophers who worry about what it could mean to eat a sandwich or watch *Seinfeld* voluntarily, absent any kind of context, are systematically misusing ordinary English. As he put it, they engage in an “unwitting extension of the ordinary sense of ‘voluntary’ and ‘involuntary’ ” (Ryle, 1949: 69). The conclusion that Ryle drew from these and other considerations was that there is no problem of free will. The appearance of the problem arises only when philosophers misuse ordinary language words such as *voluntary*. The whole problem just dissolves under ordinary language analysis.

Limitations of the Ordinary Language Approach

The ordinary language philosophers tended to be less likely to make use of formalisms for characterizing the meanings of words or sentences. The nature of ordinary language analysis was such that it produced accounts of word or sentence meaning that tended to be less rigorous than those produced by philosophers working in the ideal language tradition. Furthermore, the use theories of meaning pursued by ordinary language philosophers had little to say about the relationship between language and reality, and were thereby limited in their ability to account for reference and truth conditions, whether in scientific, philosophical, or ordinary discourse. The ordinary language philosophers demonstrated many of the important and subtle ways in which philosophically interesting words are employed in ordinary language, but they did so at the price of having neither a systematic, precise account of meaning nor a theory of the relationship between language and the world.

The ordinary language tradition ultimately met its demise at the hands of its own adherents. In his 1967 lectures on ‘Logic and Conversation,’ Grice (1989) gave a strong voice to many philosophers’ growing misgivings about the project. He argued for a sharp distinction between what is said by a speaker on a particular occasion and what the speaker might have meant by what was said. For Grice, what is said is the literal, truth-evaluable, relatively invariant portion of meaning. To use one of his examples, suppose Alyssa happens upon Cliff, who has run out of gas on the highway, and utters:

(8) There’s a gas station around the corner.

What Alyssa has said, in Grice’s sense (literally expressed, truth-conditional meaning) is the proposition that around the indicated corner is a gas station. Alyssa said nothing further about whether the gas station is open, has gas to sell, and so on. But assuming she is sincerely trying to help Cliff out, it will be inappropriate for her to use that sentence unless she

believes that the gas station is open and has gas to sell. Based on this latter observation, an ordinary language philosopher might be tempted to conclude that these further conditions are part of the meaning of (8). But that, Grice argues, is a mistake.

Grice’s alternative is that the further propositional content about the gas station being open and having gas to sell is not part of the literal meaning of (8), but is what he called a conversational implicature. This conversational implicature is part of what Alyssa means to communicate with (8), but she expects Cliff to be able to pick up on it without requiring her to state it explicitly. The details of how Cliff might do that is beyond the scope of the current discussion (see Grice, 1989; Sperber and Wilson, 1995), but to get a sense of the reasonableness of the distinction between what is said and what is conversationally implicated, consider how Alyssa could have tacked an extra clause onto (8) to take back both what she implicated and what she said.

Clauses That Cancel Implicatures

- (9a) There’s a gas station around the corner, but it’s not open.
- (9b) There’s a gas station around the corner, but it’s out of gas.

The sentences in (9) both have (8) embedded in them, and the fact that they do not seem contradictory indicates that the material in the final clause must not be opposed to any part of the meaning of (8). Now suppose Alyssa had instead uttered one of the sentences in (10).

Clauses That Contradict What Is Said

- (10a) There’s a gas station around the corner, but it’s not a gas station.
- (10b) There’s a gas station around the corner, but it’s not around the corner.

The fact that these sentences are clearly contradictory indicates that the added clauses must be opposed to some part of the literal meaning of (8). So there is strong intuitive support for the distinction between what Alyssa has said, as shown by the contradictory clauses in (10), and what she conversationally has implicated, as shown by the noncontradictory clauses in (9).

On the basis of this distinction, Grice argued for caution when moving from facts about how words are used to facts about the meanings of those words. It would have been inappropriate for Alyssa to utter (8) if she thought the gas station was closed, but that does not tell us anything about what (8) means. Evidence about use can, in principle, indicate something about the literal meaning of words and sentences, but not always in such a simple way. Ryle, in particular, was

probably wrong to jump from facts about the use of the word *voluntary* to facts about its meaning (and then to the denial of the problem of free will). Grice thought that ordinary language analysis could still be useful but that philosophers needed to pay more attention to separating what an expression can be used to communicate from what that expression actually means in the language – a project that turns out to be exceedingly difficult (*see Semantics–Pragmatics Boundary*).

The Cognitivist Tradition

Language is a fascinating topic of study in its own right, regardless of its role in helping philosophers do their work. It is now clear that the production of even very simple speech behaviors is far more complex than was once thought and working out how linguistic knowledge is structured and processed in the human mind should be a central goal in the scientific study of language. That is what linguists working in the cognitivist tradition tend to think. According to them, the goal of linguistic inquiry is not primarily to account for reference and truth or to characterize conventions of use but rather to find out what it is about the human mind that makes language what it is. Cognitivism is actually a cross-disciplinary tradition concerned with the study of the human mind in general, not just language. Leading figures in the birth and early development of the cognitivist tradition included computer scientists (e.g., Marvin Minsky; psychologists (e.g., George Miller), linguists (e.g., Noam Chomsky, and philosophers (e.g., Hilary Putnam, Jerry Fodor, Daniel Dennett).

There are four features that, taken together, loosely define the cognitivist approach to the study of mind and language: (1) an adherence to computational and representational theories of mind, (2) a rejection of most forms of behaviorism, (3) an openness to empirical evidence from a wide variety of sources, and (4) a tendency toward identifying linguistic meanings with mental states rather than with things in the world or patterns of ordinary use. Each of these aspects is discussed next.

Computational and Representational Theories of Mind

Cognitivists model the mind/brain as an information processing system that performs computations on structured representations of the world. In other words, the mind/brain is a kind of computer, analogous in many ways to a digital computer. Many people find this claim jarring at first, but actually it is quite natural to suppose that, at least in some circumstances, people use computers to do their thinking for

them. Whenever an accountant uses a spreadsheet to prepare tax forms, a pilot flies using an automatic guidance system, or a librarian searches an electronic catalog, computers are being used to perform tasks that would require mental effort if performed by human beings. When people use a computer to perform a task, they avoid some of the thinking that would have been required if they had performed the task unaided.

Digital computers accomplish their apparently mental feats by executing algorithms that manipulate data structures. An algorithm is a set of fully explicit, step-by-step instructions for accomplishing a given task, and a data structure is a package of information about some aspect of the world. For example, a data structure might contain information about a social hierarchy, the layout of a city, or the structure of a sentence. Algorithms contain instructions for how to use those data structures to decide, for example, who to approach for a loan, how to get from downtown to the suburbs, or what a speaker might mean by uttering a particular sentence. Cognitivists claim that human thought consists of computational processes (analogous to algorithms) that operate on mental representations of the external world (analogous to data structures), although there remains much debate over the nature of those processes and representations.

Like a digital computer, the mind/brain can be analyzed at a number of different levels (Dawson, 1998; Marr, 1982). At the physical level, digital computers are instantiated in electronic circuitry and minds are instantiated in brains. By investigating the brain, we can figure out what kinds of mental representations and computational processes it supports and what parts of it may or may not be involved in language. At the algorithmic level, digital computers run programs that specify the details of their behavior. The bold conjecture of cognitive science is that minds are the programs that run on the physical circuitry of the brain. By performing psychological experiments, we can shed light on how linguistic knowledge is represented in the mind and what computational processes are involved in using that knowledge. Finally, there is the task level. The programs that digital computers run can only be made sense of in light of knowledge about their connections to the world and the tasks they were designed to solve. Similarly, in order to understand how the mind uses language, it is necessary to have a theory of what language is and what knowledge is involved in language use.

These three levels of analysis thus define a multi-disciplinary program of research into the nature of human language, with different research questions

posed at each level (see Table 1). Cognitivist linguists focus most of their attention on the algorithmic and task levels, concentrating on the difficult problems of identifying the knowledge required to produce well-formed grammatical utterances, determining how that knowledge must be represented in the minds of the speakers, and identifying which elements of that knowledge are learned and which are innate (see **Innate Knowledge**). But as cognitivists, they remain open to, and sometimes make use of, evidence from the physical level as well.

The Rejection of Linguistic Behaviorism

Prior to the establishment of the cognitivist tradition in the 1960s and 1970s, the dominant approach to the study of the mind and language was behaviorism. Many philosophers at the time endorsed or were influenced this approach, including prominent representatives of both the ideal language and ordinary language traditions. Behaviorism comes in a number of varieties (see **Behaviorism: Varieties**), but what all behaviorists agree on is a rejection of internal mental states as something that can be scientifically studied or appealed to in explanations of language and behavior. For psychologists such as B. F. Skinner, this meant that linguistic behavior was to be explained as a complex pattern of responses to environmental stimuli. Verbal responses were thought of as being under the control of certain stimuli in the environment (Skinner, 1957).

Skinner's view of language was subjected to ruthless criticism from Chomsky, who pointed out the complexity of linguistic behavior and the wide variety of possible responses to a given stimulus:

A typical example of stimulus control for Skinner would be the response to ... a painting with [the utterance] *Dutch*. ... Suppose instead of saying *Dutch* we had said, *Clashes with the wallpaper, I thought you liked abstract work, Never saw it before, Tilted, Hanging too low, Beautiful, Hideous, Remember our camping trip last summer?* (Chomsky, 1959, p. 31)

Table 1 Three-level research program

Level	Questions
Task	How are natural languages structured? What must people know and what must they know how to do in order to produce and understand human speech?
Algorithmic	How is knowledge of language represented in the mind? What computational processes are involved in producing and understanding speech?
Physical	How are these representations and computational processes implemented in the hardware of the brain?

Once the nonstimulus-bound nature of linguistic behavior is fully appreciated, said Chomsky, the prospect of arriving at an account of linguistic behavior without involving an appeal to mental states is completely hopeless. Cognitivism pointed the way out of behaviorism by providing a method of formally characterizing those mental states.

The Open Evidence Base

The cognitivist tradition is an empirical tradition. The sources of evidence available to the linguist include the judgments of native speakers, the process of first-language acquisition, the controlled psychological study of speech production and comprehension, the study of acquired and genetic language deficits, and the study of the neurological features of language use in healthy adults, to name but a few. These sources of evidence can be used to investigate language at the task, algorithmic, and physical levels (see Table 2). This is not to say that it is the current practice of linguists to make use of all of these sources of evidence. Indeed much work in theoretical linguistics proceeds using only the grammaticality judgments of the linguists themselves. But there is a general commitment both to the idea that a complete theory of language has to be consistent with all these sources of evidence and to the idea that the evidence base for linguistics is open – that is, there are no principled limits on the kinds of evidence that might bear on the structure of linguistic knowledge.

The commitment to an open evidence base has important consequences. For behaviorists, the study

Table 2 Sources of evidence for the three levels

Level	Example sources of evidence
Task	Judgments of native speakers Which strings of words are grammatical and which are not? What meanings can a sentence have and not have?
Algorithmic	Developmental psychology How do children acquire language? What are the common patterns of language development? Cognitive psychology How do adults react to linguistic stimuli under controlled conditions?
Physical	Clinical studies What kinds of brain injuries and diseases cause language deficits? What specific language deficits are caused by specific brain injuries and diseases? Anatomical and functional studies What parts of the brain are involved in language use? How are these parts interconnected?

of language had to be grounded in observable behavior only. As Quine (1960) pointed out, it turns out that this leads to the conclusion that linguistic knowledge and meaning cannot be unambiguously determined. From this, he drew the conclusion that there is simply no fact of the matter about how to specify the mapping from words and sentences to their meanings (see **Indeterminacy, Semantic**). A famous response to Quine, again from Chomsky (1969), is based on the notion of the open evidence base. According to Chomsky, Quine reached his radical conclusions about semantic indeterminacy by accepting in advance the behaviorist notion that only observable behavior and responses to environmental stimuli may be used as the data for theories of linguistic meaning. But, as Chomsky points out, no other science places such *a priori* limits on the kinds of evidence that can be used to decide between competing theories. As long as the evidence base in linguistics remains open, the possibility of discovering further evidence that will help determine linguistic meaning is open as well.

Meanings as Mental States

The establishment of a viable theory about mental states and mental processing opened the door to a new class of theories of linguistic meaning based on the pairing of words in the public language with mental states of speakers. The general idea of a mental state theory of meaning is at least as old as Aristotle (see **Aristotle and Linguistics**), but the computational and representational theory of mind gave it new life by providing a story about what mental states might be like and how they might be processed in the mind. In addition to endorsing a mental state account of meaning, some cognitivists also harbor a deep mistrust of the reference-based theories pursued in the ideal language tradition. The semanticist Ray Jackendoff (2002) argues that the only kind of reference a cognitivist theory of language can countenance is reference to other mental states, whereas Chomsky (2000) suggests that reference, as originally construed by ideal language philosophers, is not a suitable topic for scientific inquiry at all.

Jerry Fodor (1975) has proposed that words and sentences come by their meaning through being paired with internally represented formulae in what he calls the Language of Thought, or Mentalese (see **Mentalese**). Mentalese is not a public language such as English. It is more like a computer language – a formal system with a combinatorial syntax and an expressive power that equals or surpasses that of a public language. Fodor proposes that words and sentences express mental states, but, unlike

Chomsky and Jackendoff, he takes the further step of attempting to scientifically characterize the meanings of expressions in Mentalese as relationships to objects and properties in the external world (see **Representation in Language and Mind; Causal Theories of Reference and Meaning**). Fodor's theory of meaning thus has two parts: (1) words inherit their meanings from the mental states they express, and (2) most of those mental states get their meanings through reference to the external world. An important alternative cognitivist account of meaning as mental states is offered by connectionism, although a full discussion of that approach is beyond the scope of this article.

The Limitations of Cognitive Science

It is not yet clear how far cognitive science can go, and there are philosophers who dispute the claim that studying the structure and processing of linguistic knowledge in the human mind can tell us much about the nature of language itself (see Barber, 2003). But the computational and representational theory of mind, as a working hypothesis, has given rise to a productive research program producing theories of mind and language rich and predictive enough that, at the very least, they should not be ignored. The cognitivist approach to the study of mind and language is widely regarded by philosophers as the only approach currently worth taking seriously.

The New Philosophy of Language

The new philosophy of language emerged in the 1970s as a synthesis of the ideal language, ordinary language, and cognitivist traditions. From the ideal language tradition comes the use of rigorous formalisms and a concern for the connection between language and reality. From the ordinary language tradition comes the descriptive nature of the project and careful attention to the nuances of ordinary use, as well as Grice's distinction between what is said and what is implicated by an utterance. And from the cognitivist tradition comes an adherence to computational and representational theories of the mind, a rejection of linguistic behaviorism, an attention to the mental states of the language user, and a concern with making semantic and pragmatic theories consistent with the relevant empirical results concerning language and the mind.

The boundaries between linguistics and the philosophy of language have become blurred in this new synthesis. Whereas phonology (the sounds of language), morphology (the structure of words), and syntax (the structure of sentences) remain a concern

mostly of linguists, semantics (the meaning of language) and pragmatics (the communicative use of language) are studied by both linguists and philosophers. There has also been considerable cross-fertilization between linguistics and philosophy. Linguists have adopted the formalisms of the ideal language tradition and the Gricean view of the relation between semantics and pragmatics that arose out of the ordinary language tradition. Philosophers, on the other hand, have adopted the linguistic account of syntax and feel an obligation to relate the semantic interpretation of a sentence to its syntactic form. In addition, the cognitivist approach to linguistics also throws up a host of difficult conceptual issues that demand a rigorous philosophical treatment (*see Philosophy of Linguistics*), for example, the place of reference in semantic theory (*see Externalism about Content*), the nature of linguistic knowledge (*see Innate Knowledge; Tacit Knowledge*), and the connection between language and thought (*see Thought and Language: Philosophical Aspects*).

Two More Theories of Proper Names

How might a practitioner of the new philosophy of language tackle a traditional semantic problem such as the content of proper names? Two theories of proper names are presented by Tyler Burge (1973) and Larson and Segal (1995). These two theories agree with one another in many important respects – so much so that we might be tempted to suppose that they are merely variants of one another. But, as Gabriel Segal (2001) points out, there are a number of pieces of relevant evidence from the task, algorithmic, and physical levels of cognitive analysis that may be used to adjudicate between the theories. (A caution: The semantic issue is actually more technical than the following discussion suggests, concerning points of difference between semanticists working in the formal framework of truth-theoretic semantics. Because there is no room to introduce the details of that framework here, the accounts of the rival theories are somewhat sketchy, although, I hope, detailed enough to make it clear how empirical evidence can be used to decide between them.)

Burge's approach to proper names is a variation on Russell's disguised definite descriptions. Burge proposes that proper names are actually a kind of common noun, that is, words such as *table* and *cat* that encode properties that apply to large numbers of objects. In Burge's account, if we have a cat named *Sylvester*, then that object has both the property of being a cat (a property it shares with other cats) and the property of being a Sylvester (a property it shares with other Sylvesters). In defense of this idea, Burge

points out that, like common nouns, names can be pluralized and paired with determiners such as *the* and *a*:

- (11a) There are very few Sylvesters in the world.
- (11b) There were three Madelines at the party.
- (11c) There's a Bartholomew Kropotnik here to see you.
- (11d) The Jessica I met today was a real jerk.

This idea encounters an immediate difficulty. Burge says that names are common nouns, even when they occur unmodified and on their own:

- (12) Fido wants to chase Sylvester.

But other common nouns cannot be used that way in English:

- (13) *Dog wants to chase cat.

Sentence (13) only works if we interpret *dog* and *cat* as unusual names rather than as common nouns. So proper names seem to be unlike common nouns in at least this respect. Burge resolves the discrepancy by suggesting that bare, unmodified names actually have hidden determiners attached. A name such as *Fido*, when used on its own is, unbeknown to the speaker, actually the phrase *That Fido* or *The Fido* in disguise.

The rival view is Segal's contention that proper names are not common nouns but instead are a special kind of word, paired in each speaker's mind with a special kind of mental representation – an individual concept. These individual concepts are mental representations that encode information about the individuals named. So the name *David Bowie* is paired with an individual concept of David Bowie, perhaps containing the information that he sings, plays the saxophone, is married to a runway model, has probably had plastic surgery, and so on. Names, in Segal's account, are not at all like common nouns, encoding predicates that can apply to more than one person. Rather, they are labels that attach to conceptual information about particular individuals. There are not many David Bowies sharing one name. Rather, there are potentially many names *David Bowie*, each linked to a different individual concept.

Empirical Evidence

It might seem that in the end, the differences between the two theories do not amount to much. Burge says that the name *Fido* can be applied to anything that is a Fido, whereas Segal says that it only applies to one individual and that the reason why there seem to be so many Fidos is that there are many names for distinct individuals that happen to sound the same (call

these names *Fido*₁, *Fido*₂, etc.). Is there any real difference between these two theories? A behaviorist such as Quine might be inclined to think that, as long as each can be integrated into a larger theory of equal power in predicting linguistic behavior, then there is no fact of the matter about which is correct. But a cognitivist would rather suppose that there is a way to tell how the language system works, reflected in the biology and psychology of language, and that at most only one of the two suggestions can be correct. And it seems, at least at first glance, that the evidence from the task, algorithmic, and physical levels supports Segal's theory over Burge's.

At the task level, cognitivists consult the intuitions of native speakers to determine the characteristics of the language that they speak. In the case of proper names, the two theories under consideration make different predictions about the syntax of English. Burge's theory predicts that bare names actually have a hidden determiner word attached to them. But this view has some trouble accounting for common intuitions about how names and common nouns can be used. For example, why is it that determiners can go unpronounced when attached to names, but not when attached to common nouns, as shown by (13)? And why is it that sometimes special contexts are required to insert the determiner in front of a name? For example, to the question "Where do you live?" the response in (14a) seems natural whereas (14b) sounds awful. If *Saint Louis* is really short for a phrase such as *that Saint Louis*, then why can we not say (14b)?

(14a) I live in Saint Louis.

(14b) *I live in that Saint Louis.

At the algorithmic level, cognitivists look at psychological evidence regarding how linguistic knowledge is represented and processed. Again, the two theories make different predictions about the psychology of names. Burge predicts that names that sound the same are the same name, whereas Segal predicts that each individual's name is distinct. If Segal is right, there should be evidence that people tend to expect identical-sounding names to apply only to a single individual. Again, there is some evidence that supports Segal's prediction. It seems that children learning English as a first language expect there to be a class of nouns that refer to only one thing and make use of syntactic clues such as the presence or absence of determiners to decide whether to apply new words to other objects or not. For example, when told that a novel object is *wuzzle* (with no determiner), children are reluctant to apply the new word to other novel objects, even when they are highly similar to the original. But when told that the novel object is *a wuzzle*, they will happily generalize

the term to other objects that seem to share some salient properties with the original – just like ordinary common nouns.

Burge's theory also predicts that names are **not** a special kind of noun, whereas Segal predicts that they are. If Segal is right, we should expect to find psychological differences between names and common nouns. We might also expect some physical-level differences. (Recall that at the physical level, cognitivists look to neurological evidence for or against the kinds of representation and processing they propose in their algorithmic-level theories.) Again, the evidence seems to support Segal's view over Burge's. As previously noted, children seem to be prewired to look for names as well as common nouns. In addition, psychological studies on adults reveal that proper names are much harder to recall than common nouns, suggesting distinct storage and/or processing. And at the physical level, certain kinds of brain damage can cause people to lose their ability to use proper names while leaving their ability to use common nouns intact, and vice versa. This strongly suggests that names are a special kind of word stored in a separate area of the brain.

In fact, things are not as bad as all that for Burge's theory. Segal (2001), in his much more complete and sober account, correctly points out that the psychological and neurological evidence is still quite sketchy and open to interpretation. It is quite possible that a committed Burgian could find a way to keep the common noun theory of names alive. The main point of this example has been to show how, in principle, multidisciplinary evidence from all three levels of cognitive analysis can bear on an issue in semantics. Whereas a behaviorist might be content with two theories that are equally good at describing some aspect of linguistic behavior, the new philosopher of language looks deeper to try and find out which theory does a better job of accounting for the cognitive aspects of language.

Final Words

The work on proper names reviewed here nicely illustrates the main features of the new philosophy of language. Burge and Segal's truth-theoretic approach to semantics is as rigorously formal as any theory in the ideal language tradition; the attention to ordinary speaker intuitions in mediating between semantic theories echoes the approach of the ordinary language philosophers; the mentalistic nature of the theory, the formal, computational nature of truth theories, and the openness to evidence from all levels of cognitive analysis clearly places the work in the cognitivist tradition.

But is this new hybrid approach really philosophy of language, or is it just a branch of linguistics or psychology? There are still those who hold out the hope that analysis of language will eventually help with the resolution of issues in other branches of philosophy, even if only in providing a starting point, and most contemporary philosophers of language remain sensitive to the philosophical puzzles and paradoxes that drove the ideal and ordinary language philosophers. Indeed, one of the selling points of both Burge's and Segal's theories of proper names is that they can account for the meanings of empty names. But heeding Grice's lesson about the difficulties of determining what is said and heeding the lessons from contemporary linguistics about the complexities of ordinary language, few still believe any philosophical problem will be solved or dissolved with just a little bit of armchair reflection on conventions of use. The new philosophy of language promises progress on some of the difficult traditional problems in philosophy of language (and perhaps on more general philosophical problems) by combining careful conceptual analysis with detailed attention to empirical results from the scientific study of language, the mind, and the brain.

Communication: Semiotic Approaches

The Rise of a Controversy

The topic at issue in this article shows several problematic aspects. In communication research, we are presently crossing a phase of intensive innovation, in which the paradigm and the role of the different disciplines are changing remarkably. For a long time, the leading role in this area was played by the *sciences du langage*, in particular by semiotics and linguistics. Nowadays, this role is played by a complex epistemological interplay, where other human and social sciences – focusing on the organizational assets of communication context – as well as technological disciplines contribute to the study of real communicative events. Thanks to these contributions, it has become evident that real communicative events are not only influenced, but functionally governed by their actual context (enterprises, institutions, communities, and other social organizations . . .) and by the media, by which they are not only broadcasted, but also structured.

Moreover, even linguistic sciences, which are expected to explain the internal structure of a communicative event, are largely adopting a model of communication whose conceptual frame is no longer essentially semiotic, but rather pragmatic. The prevailing of a pragmatic paradigm seems to have strongly redimensioned the semiotic claim. More specifically, both major trends – Speech acts Theory and Relevance Theory (i.e., the ostensive inferential model of communication) – are proposing a vision of communication that does not focus on semiotic aspects.

While the former of these trends has developed its own model essentially ignoring the semiotic approach (Austin, 1962 and Searle, 1969), the latter has created a proper controversy, initiating a sort of campaign against the semiotic approach and its academic power.

At this point, it is useful to outline the ostensive-inferential model of Relevance theory synthetically, in order to specify its criticism of the semiotic model of communication, and also what it justly presupposes a semiotic model to be. In fact, the ostensive-inferential model, whose roots are Paul Grice's and David Lewis' works (Sperber and Wilson, 1995/1986: 2) is introduced by means of those aspects that oppose it to the semiotic model (Sperber and Wilson, 1986: 6) "The semiotic approach to communication (as Peirce called it and we will call it ourselves), or the semiological approach (as Saussure and his followers called it), is a

generalization of the code model of verbal communication to all forms of communication," and is thus to be abandoned, since it does not seem to explain the real functioning of communicative events: "The code model of verbal communication is only a hypothesis, with well-known merits and rather less well-known defects. [. . .] Its main defect, as we will shortly argue, is that it is descriptively inadequate: comprehension involves more than the decoding of a linguistic signal" (Sperber and Wilson, 1995/1986: 6). In other words, the semiotic approach appears to interpret communication as a process where a speaker constructs a message by coding a certain meaning by means of a linguistic system, and transfers it to a hearer who simply **decodes** it, thus retrieving its original meaning. The roles of the speaker and the hearer in a communicative event are thus reduced to coding and decoding respectively. The scholars of the ostensive-inferential approach to communication, relying on wide and unquestionable evidence, argue that the process of interpreting a message by the hearer is far more complex, and that the semiotic component represents a rather short stretch of the communicative process.

The semiotic component is neither necessary nor sufficient to explain the process of communication.

Firstly, it is not necessary because many messages do not make use of a linguistic system; very often, the communicator addresses the hearer not through words of a certain natural language, or through another semiotic system, but through traces by which the hearer is expected to be guided to infer the communicative intention of the message. Sperber and Wilson (1995/1986: 25) argued in fact that Grice's originality consisted in suggesting that the identification of the communicator's intentions is **sufficient** for the achievement of successful communication, and the mediation of a verbal code is not necessarily needed. The authors give an example (Sperber and Wilson, 1995/1986: 25–26) that shows how communication may succeed even without the help of the coding-decoding process. If Peter asks Mary: 'How are you feeling today?', Mary may answer by pulling a bottle of aspirin out of her bag and showing it to him. Although there is no code or convention that rules the interpretation of her behavior, this action can be taken as strong evidence that she wants to inform Peter that she does not feel well. In this sense, Mary and Peter can be said to have communicated, even if they have not made use of any verbal or nonverbal code.

The semiotic component is not even sufficient, even in the very usual cases where it is present. However, large it may be, interpretation requires that various

contextual aspects are involved in order to complete the information carried by the semiotic component: “Verbal communication is a complex form of communication. Linguistic coding and decoding is involved, but the linguistic meaning of an uttered sentence falls short of encoding what the speaker means: it merely helps the audience infer what she means” (Sperber and Wilson, 1995/1986: 27). Within this complex form of communication, the results of the decoding process are considered a piece of evidence from which the hearer, through a noncoded mechanism, can infer the speaker’s intentions. In this sense, the semiotic component becomes subservient to the inferential process. Using the terminology of Relevance Theory, an enrichment of the linguistic form of the message is however indispensable to obtain the semantic and pragmatic interpretation of a message. This is crucial to distinguish between ‘sentence’ and ‘utterance of a sentence.’ According to these authors, generative grammars fail to consider that a certain sentence may appear in an enormous variety of utterances that, though sharing a ‘core of meaning’ (Sperber and Wilson, 1995/1986: 9) bound to the linguistic code, each includes a different non-linguistic, context-bound meaning that can be neither predicted nor ‘calculated’ through a decoding process. Therefore, an inference process is required in order to grasp a complete representation of the communicator’s intentions. To give just an example (adapted from Sperber and Wilson, 1995/1986: 11), a sentence like ‘You’re leaving’ contains different levels of noncoded meaning: (1) an indexical (you) whose interpretation depends on the actual communicative event where the sentence is uttered; and (2) a set of possible interpretations: is the speaker informing the hearer that she is to leave? Is she making a guess? Or is she rather expressing disappointment because he is leaving?

Thus, the process of comprehension, through which the hearer reconstructs the communicator’s intentions, is not a decoding process, but rather an inferential process. Whereas the decoding process “starts from a signal and results in the recovery of a message which is associated to the signal by an underlying code” (Sperber and Wilson, 1995/1986: 13), an inferential process starts from a set of premises and reaches a conclusion warranted by the premises themselves. Among possible interpretations of an utterance, the hearer chooses the most adequate to certain expectations of truthfulness, informativeness, and comprehensibility. The inferential process of comprehension is an essential component of communication, which is nonetheless often integrated by the employment of a code. A common code between the interlocutors turns out to be the most powerful, however not indispensable, tool for communicating.

Sperber and Wilson’s critical remarks are generally convincing and acceptable, where they criticize the attempt to explain the interpretative process merely in terms of decoding. Less convincing is the more general criticism of all semiotic models of communication, accusing them of reducing communication to a coding and decoding process.

Saussurean ‘Signification’ as Keyword and Sign of Contradiction

Our thesis is that Sperber and Wilson’s criticism, which is legitimate in relation to certain semiotic models, is unacceptable for others. Furthermore, in our opinion, their reductive vision of the function of the semiotic component within a communicative process is by no means convincing.

For both points, we should briefly reconsider some of the communication models more or less explicitly proposed by semioticians and linguists in the past century. It is almost compulsory to start by referring to Ferdinand de Saussure, with whom the beginning of modern linguistics in its structuralist phase is usually connected. His representation of the communication process seems to constitute a typical coding and decoding model, **Figure 1**.

Here the speaker, having in mind a particular *signifié*, correlates it to the corresponding ‘signifiant’ of her linguistic system (*langue*), which is perceived by the hearer who correlates it to the correspondent *signifié* of the same linguistic system. Nonetheless, Saussure’s *Cours* has a problematic nature; its real function is to witness a deep and complex meditation rather than systematically expounding a theory. Thus, beyond the approximate presentation of the discourse circle (*circuit de la parole*), the Saussurean text introduces the fundamental but problematic distinction between *signifié* – defined as a meaning carried by an element of a *langue* (a linguistic system) – and *signification* – a term denoting a notion that remains rather opaque in the Saussurean text. Its interpretation and the evaluation of its role in Saussure’s doctrine is nevertheless crucial, and turned out to characterize the two main divergent trends that emerged within post-Saussurean structuralism. It is worth noticing that these two trends have developed

Figure 1 Ferdinand de Saussure’s model.

considerably different attitudes toward communication in their theoretical elaboration. Relevant representatives of both trends being numerous, only those scholars who cover significant and universally acknowledged cruxes will be mentioned here.

The Functionalist Reading

Let us consider Saussure's text. In a passage in chapter IV of the second part of the *Cours de linguistique générale* (1916/1995: 158–159), Saussure seems to employ the term *signification* as equivalent to *signifié*: *signification* seems to be nothing but the counterpart of the auditive image, “*un des aspects de la valeur linguistique*” or, better, the value of the conceptual component of the linguistic sign. Nonetheless, in the following passages, Saussure opposes *signification* to *signifié* throughout a series of interlinguistic confrontations (*mouton* vs. *sheep* and *mutton*, French plural vs. Sanskrit plural and dual, etc). So, without explicitly saying it, Saussure employs *signification* as opposed to *signifié*; interlinguistic comparisons between different language-bound *signifiés* are possible thanks to a conceptualization of reality that is formed somehow independently of these *signifiés*. This distinction lets us guess the existence of a complex correlation between the two semantic dimensions (reasonably understood as interpretation), which goes from the *signifiés* obtained through the coding to the *significations*, which articulate the *parole* (the speaker's actual message). Without this conceptualization, evoked by the use of the term *signification*, such a comparison between different languages would be simply impossible (on this point, see Rigotti & Rocci, in press). *Signification*, thus, has to be interpreted as an inter- or translinguistic category independent of the linguistic code, however correlated to it. If we integrate this notion into the Saussurean *circuit de la parole*, we obtain a more comprehensive model of communication, where the correlation of *signifiant* and *signifié* is only a stretch of a more complex path, starting with the actual meaning intended by the speaker, and ending with the reconstruction of this meaning tentatively operated by the hearer.

The interpretation of the Saussurean text presupposed by this model is explicitly adopted by N. Troubezko in his *Grundzüge der Phonologie* (1939), where the *signifiés* are considered, at the level of *langue*, as abstract rules and conceptual schemes, which need to be related to the actual *significations* emerging from language use (see also Rigotti & Rocci, in press: 5). On this point, M. Bréal (1844–1995: 552b) observes that, where we need to employ a certain word in communication, we ‘forget’ all possible meanings of that word except the one that corresponds to our thought (“*s'accorde avec notre pensée*”). Although the other meanings are

still somehow present to our mind, we choose the one that corresponds to the meaning we want to express – i.e. to the *signification*. Here, the relation between *signifiant* and *signifié* is certainly not a coding-and-decoding one, since it is mediated by the speaker's choice to her communicative intention. The same approach to communication may be found in Karl Bühler's *Organonmodell*, as outlined in his *Sprachtheorie* (1934). Among the numerous pages of Bühler's text, which could be useful to elucidate his position on this issue, one passage seems particularly revealing (1934: 63), where Bühler argues that no code can ensure the correct interpretation of the word ‘horse’ as it is used in a text, where it can refer to a single entity or to the species of horses in general. The use within a text is not “*morphologisch erkennbar*,” i.e., it cannot be decoded by means of morphological aspects of the language, neither in Latin, a language that does not foresee articles, nor in the Indo-Germanic, article-provided languages. What allows us to correctly interpret the use of the word ‘horse,’ is a ‘detective-attitude’ towards the context of the communicative event, which aims at evaluating what the speaker has in mind: “Man muss es detektivisch gleichsam dem Kontexte oder den Umständen der Sprechsituation entnehmen, ob der Sprecher das eine oder das andere im Auge hat und meint.” Moreover, an author to whom Bühler is quite indebted, Philipp Wegener, had also stressed the interpretative aspect of communication 50 years previously. Wegener argues that the hearer has the complex task of understanding the speaker's action; for this purpose, he has to figure out what the ‘goal’ of the communicative action may be. Comprehension of verbal messages is achieved through ‘inferences’ (*Schlüsse*), which rely both on the meaning of the verbal signs as well as the experience of reality. So, where experience is lacking, comprehension is impossible (Wegener, 1885–1991: 128). For instance, one could not understand a sentence such as ‘a whistle of the train, and my brother was gone,’ if one had no experience of a train setting off from a station.

If, speaking of a semiotic approach to communication, we refer to this research tradition in linguistics and semiotics, the criticism put forward by the scholars of Relevance Theory loses its bite: in fact, the process of communication is not referred to as a coding-decoding process within this trend. Rather, one should acknowledge that the process of communicative inference is constantly associated with the concept of interpretation.

Nor would the objection be acceptable that, in these models, inference only plays the subservient role of integrating the semiotic process. Here, it must be noticed that, if inference is acknowledged as

a necessary integration of the semiotic component, it follows that the semiotic component itself is not considered sufficient for the accomplishment of the communicative event. Therefore, the inferential component becomes essential for communication. More specifically, in this first tradition, neither the speaker's coding nor the hearer's decoding hold the supremacy in the communicative process; the crucial moment is rather when it becomes clear what the speaker intended to communicate, and the hearer understands it. As Bühler claims, on the backdrop of a Husserlian philosophical vision, language always appeals to the speaker's knowledge of reality; and each time we understand the meaning of a communicative event, we deeply and unavoidably rely on a 'reality-driven selection' (*sachgesteuerte Selektion*, Bühler, 1934: 65), which constitutes the core of communication. Not by chance, a large part of Bühler's research is devoted to the study of the specific semantic mechanism of the 'indexicals' or 'deictics' (*Zeigwörter*). This term refers to linguistic units and structures whose meaning is reconstructed through the identification of an aspect of the communicative situation (Bühler, 1934 see in particular p. 107).

Here, given the importance that Bühler attributes to reality in the process of communication, it becomes clear why he adopts a 'triadic' notion of the sign, which is rather innovative if we compare it to other

structuralist models. In his *Organonmodell* (1934: 24), the sign is conceived as an 'instrument' for communicating; and communication is interpreted pragmatically, as an action accomplished by the speaker and the hearer. According to Bühler (1934: 52), communication must be viewed as a human 'action,' vitally bound to other meaningful human behaviors. Communication is related to other actions, and is an action in itself. In particular, Bühler distinguishes between *Sprechhandlung* (1934: 53), which is the human activity of communicating, i.e., the Saussurean *parole*, as opposite to *Sprachgebilde* (the *langue*, 1934: 57); moreover, with the notion of *Sprechakt* (1934: 62), he focuses on a single communicative action, and with *Sprachwerk* (1934: 53), he denotes the linguistic products resulting from a single human action of communicating.

Within the model, the sign is related to the speaker (*Sender*), the addressee (*Empfänger*) and the objects and states of affairs in reality (*Gegenstände und Sachverhalte*). The sign is bound to each dimension by a specific relation: with regard to the speaker, the sign is a 'symptom,' bound by a relation of 'expression' (*Ausdruck*); with regard to the addressee, the sign is a 'signal,' and stands in the relation of appeal (*Appel*); and, finally, with regard to the object, the sign is a 'symbol,' and stands in the relation of 'representation.' The following diagram, **Figure 2**, illustrates Bühler's model (1934: 28):

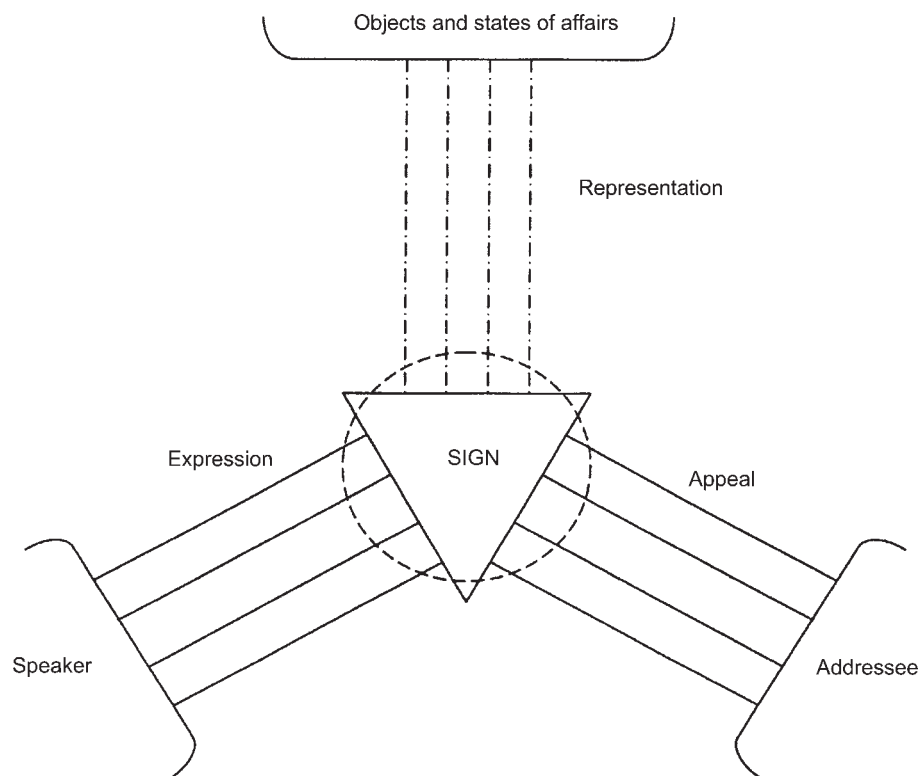

Figure 2 Karl Bühler's *Organonmodell*.

Figure 3 The model of communication within the functionalist reading.

The distinction between code dimension and discourse dimension of semantics, implied by the Saussurean terms *signifié* and *signification*, is tackled and deepened by another linguist: E. Benveniste, who introduced the terms ‘semiotic’ and ‘semantic’ (Benveniste, 1966a). He underlines that the content dimension of code units is a semiotic one; while the content dimension of the same units, insofar as they are used within a discourse, is truly semantic (on this point, see also Rocci, 2003). Moreover, among the indexicals investigated by Bühler, he focuses on personal pronouns, by which the communicative act and its constituents are mirrored in specific linguistic structures (Benveniste, 1966b). The study of personal pronouns on both the diachronic and the synchronic axes brings Benveniste to single out the essential role that is played by subjectivity (*I* and *You*) in communication.

On the basis of the Saussurean notion of ‘signification,’ conceived as the actual, situation-bound meaning of the sign in the communicative process, and of Bühler’s interpretation of the sign as an instrument for communicating, we could modify Saussure’s diagram and build a model of communication that is shared in its fundamental aspects by all the authors within the research tradition we have examined so far, Figure 3.

Even in its visual diversity, the well-known model proposed by Roman Jakobson (Jakobson, 1960/1995) is, in many respects, reminiscent of Bühler’s sign model. Being evidently influenced by Shannon and Weaver’s model, it brings to light the process of transmitting a message, thus offering a rather obvious metaphor of the communicative process, Figure 4.

Jakobson’s model has two indubitable merits: firstly, it takes into account, and represents synthetically, a complex set of factors; secondly, it deepens many of the specific functions of the message in relation to

Figure 4 Roman Jakobson’s model of the fundamental factors of communication.

Figure 5 Roman Jakobson’s model of the textual functions.

each of these factors in the communication process. This Russian linguist treasures his former belonging to the significant experience of Russian formalism, by introducing the poetic function into his model, as an autotelic orientation of the message towards itself, Figure 5.

The graphic representation of Jakobson’s model appears to be richer than the sign scheme provided by Bühler. However, if we consider the model implicit in the theory of the latter, we have to recognize that Bühler’s model is richer in important respects: indeed, in Jakobson’s perspective, the pragmatic dimension is weakened; the essential role of inference in interpretation is ignored, as well as the relevance of context for interpretation. Another important aspect concerns the distinction between *signifié* and *signification*, reflecting the more general difference between language (*langue*) and speech (*parole*), which remains outside the graphic model outlined by Jakobson, even though it is adumbrated in some significant research (Jakobson, 1957).

Some Code-model Approaches

The precise definition of the Saussurean model represents a core issue for a large segment of semioticians of the past century. Indeed, besides the tradition we have tackled so far, another tradition of semiotic studies starts from a different interpretation of Saussure's *signification*. The second trend does not concentrate on the notion of *signification*, and therefore it does not focus on the textual and discursive dimension of the *parole*, whereas the point of view of the code (*langue*) is preferred. This position can be found not only in Hjelmslev's *Prolegomena to a theory of language* (1961), but also in various scholars belonging to French structuralism – among which R. Barthes plays a paradigmatic role – and in Umberto Eco's first semiotic theory, expounded in his work *Trattato di semiotica generale* (1979).

It is worth noticing that it is quite difficult to infer a model of communication from these positions. Barthes, for instance, stresses the interpretation of language as a system, whereby the individual performing a particular act of *parole* (a discourse) simply selects and actualizes one of the possible states of the system (Barthes, 1964). As the semantic dimension is exhaustively represented by the system of the *signifiés*, the meaning of communicative messages is not built by a speaker for an addressee, but it is rather one possible product the system can generate. The human subject is excluded from the communication process; communication itself, conceived as a communicative interaction between two human beings, i.e., as the junction of the communicative action of the speaker with the interpretative action of the addressee, fails to be considered at all. Umberto Eco (1979: 8) defined communication as “the passage of a signal (*not* necessarily a sign) from a source (through a transmitter, along a channel) to a destination.” This definition is meant to include both cases of machine-to-machine passages of information (see also 1979: 32), and cases where the destination (and not necessarily the source) is a human being. In the latter case, communication involves the process of signification, “provided that the signal is not merely a stimulus but arouses an interpretive response in the addressee” (1979: 32). The process of signification is not conceived as a communicative action; the focus here is on the signification system, “an autonomous semiotic construct that has an abstract mode of existence independent of any possible communicative act it makes possible” (1979: 9). Thus, it is the system that guarantees communication, and the existence of the system does not presuppose the existence of actual communicative events. On the contrary, communication between human beings necessarily presupposes a

signification system (thus excluding cases of nonverbal, ostensive communication). It must be observed that Eco explicitly discusses the problem of what the place of the human being, i.e., “the ‘acting subject’” (1979: 314) within semiotics should be. He concludes that what is outside the signification system – its “material expressions” (1979: 317) might even be “tremendously important,” but it is beyond the subject of semiotics. In fact, as Eco argues, the proper subject of signification is “nothing more than the continuously unaccomplished system of systems of signification that reflects back on itself,” whereas individual material subjects only “obey, enrich, change and criticize” the signification system (1979: 315).

As emerges from our survey of some theories within the second trend of Saussurean semiotics, speaking of a proper ‘model of communication’ in relation to them turns out to be quite difficult. In fact, communication in itself is intrinsically ignored. What they hypothesize are the mysterious workings of an autonomous semiotic program, which would auto-install and run on a mass of undifferentiated terminals, thus defining their individual or network sign production.

Charles Sanders Peirce

The model of communication of the first trend inspired by Saussurean semiotics, which we found in Bühler, and which is confirmed by recent pragmatic models, shows interesting analogies with another tradition, often considered as alternative to the Saussurean one: the semiotic model by Charles Sanders Peirce. As Bühler would do in the 1930s, Peirce had already proposed a triadic notion of sign at the end of the 19th century, **Figure 6**.

According to what Peirce wrote in 1897 (1897–1935–1958: 2.228), “A sign, or ‘representamen’ is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign

Figure 6 Charles Sanders Peirce's model of sign.

which it creates I call the interpretant of the first sign.” Although Peirce is often considered one of the founders of semiotics, it must not be forgotten that his contribution is particularly relevant from the logical and philosophical points of view. And his interest for semiotics concerns the cognitive rather than the communicative dimensions. Nonetheless, his contribution is also significant for semiotics and for a theory of communication. Concerning semiotics, we have to underline that Peirce’s notion of sign includes ‘symbols,’ as well as ‘indexes’ (bound to the object through a real connection), and ‘icons,’ which remind of objects by reproducing their features. Semiotics turns out to include both verbal and nonverbal dimensions. Nevertheless we should also consider that, within Peirce’s enormous scientific production, we find some significant cues for a significantly comprehensive communication model.

Firstly, the correlation of the sign with both subjectivities involved in communication is highlighted by the above-quoted definition, where the subject to whom the sign is addressed is explicitly mentioned and the addresser is presupposed. On this point, M. Hansen (2002) argued that Peirce’s approach implies an active involvement of the speaker and the addressee in the process of interpretation. In fact, the ‘representamen’ does not univocally imply a certain ‘interpretant,’ but it rather suggests several possible interpretations. Here, the interaction of the speaker and the addressee is necessary to evaluate the interpretation to be chosen: the context of interpretation is actively constructed by the interlocutors, on the basis of the experience of the knowledge community.

Secondly, we find in the Peircean text a truly pragmatic reading of the process of interpretation, as the ‘final interpretant’ of a sign is the ‘habit change,’ i.e., “a modification of a person tendencies toward action” (Peirce, 1897–1935–1958: 5.476; on this point, see also Rigotti & Rocci, 2001: 48).

Conclusive Remarks

We might conclude by arguing that the criticism moved against the semiotic tradition by the scholars of Relevance Theory is only valid for those semiotic approaches which can be defined as code-driven, and depend on a reductive interpretation of Saussure. They conceive of the sign as a binary unit, and thus reduce communication to a coding and decoding process. The criticism does not hold for all those, indeed rather numerous, approaches (Peirce and the functionalist interpretation of the Saussurean *Cours*: Troubetzkoy, Bühler, Jakobson, Bally, Sechehaye, Karcevskij ...), where a pragmatic (in the sense of the *Organonmodell* of language) and triadic representation of the sign

allows to understand communicative events in an adequately comprehensive perspective.

Our short survey of semiotic approaches to communication in the 20th century shows that not all of them can be considered as code-models, it also puts forward – this concerns in particular some authors like Peirce, Bühler, and Benveniste – the possibility and even the reasonableness of constructing a semio-pragmatic model of communication (Searle, 1969; Clark, 1996), concerning both the wording and the interpretation side, this latter being based on semiotic, metaphoric (Lakoff, 1980; Danesi, 2004) and inferential processing (Sperber and Wilson, 1995–1986); comprehending both verbal and nonverbal communication (Rocci, 2003), and including a theory of subjectivity as one of its relevant components (see Rigotti and Cigada, 2004). And the semiotic tradition of the 20th century could be shown to be helpful in this endeavor.

Communication, Understanding, and Interpretation: Philosophical Aspects

D Hunter, State University of New York at Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Philosophers have asked questions about both the nature and the extent of communication. What, for instance, is the difference between expressing a belief and communicating one, and what role does language play in communication? What must one know to interpret another person, and can we ever really understand another person? Philosophers are still at work refining these questions and considering answers. This discussion aims to sketch the direction of this work.

The Nature of Communication

There might seem nothing especially puzzling about the nature of communication. After all, we seem to communicate with each other all the time and succeed, largely without having to reflect on the nature of our success. We tell others what we think or believe, and they in turn tell us what they think or believe. One way to begin to see what philosophers

have found puzzling about the nature of communication is to consider whether nonhuman animals – dogs and cats, for instance – ever communicate with each other or with us.

Suppose that Fido knocks his food bowl over whenever he is hungry, and he does it only in the presence of his master, whom he then looks at intently. Is Fido trying to communicate with his master? To answer this, we need to know more about what it is to try to communicate. One initially helpful distinction is between communicating a belief and merely manifesting or revealing one. Agents manifest or reveal something about their beliefs, desires, and intentions whenever they act, and ordinarily we can explain and predict these actions by reference to what (we think) they believe, want, and intend. This applies as much to dogs and cats as to people. We might, for instance, speculate that Fido is knocking his bowl over in part because he knows it is empty and wants it to be full. We might even, somewhat more ambitiously perhaps, say that Fido knows that if he knocks the bowl around his master will fill it for him. These attitudes are manifested by Fido's actions, in the sense that we can infer from the actions that he has these beliefs and desires. But, of course, it is one

thing for an action to reveal what one believes or desires and another to communicate what one believes or desires. After all, sometimes our actions reveal more than we want, as when we let something slip or when someone is spying on us. Genuine communication, it seems, requires **intending** to reveal what one believes; it requires manifesting one's beliefs or desires on purpose. Communication is thus an intentional activity. Did Fido intend to communicate his beliefs and desires when he knocked the bowl over?

Part of the difficulty in answering this stems from an ambiguity in the phrase 'communicate what he believes'. In one sense, for Fido to communicate what he believes is for him to communicate, in this case, that his bowl is empty, that it should be full, and that he is hungry. In this sense, what is communicated are the facts, or at least the facts as Fido takes them to be. But in another sense, for Fido to communicate what he believes is for him to communicate the fact that he has those beliefs and desires. In this sense, what is communicated is the fact that Fido takes or wants the world to be some way. Plausibly, to communicate what one believes or desires in the second sense, one must be aware that one has those beliefs and desires; one might doubt whether dogs and cats are aware of their own beliefs and desires. To doubt this is not to doubt whether dogs and cats have beliefs and desires or whether their actions are caused by their beliefs and desires. One can admit all of this while still doubting whether dogs and cats have the level of self-awareness necessary for intending to reveal that they have certain beliefs and desires. It is an empirical question whether dogs and cats have this level of self-awareness. In any event, the two senses of 'communicate what one believes' differ only over what is communicated and not over what it is to communicate. So even if it is true that Fido is incapable of communicating **that he believes that his bowl of food is empty**, it might still be true that he can communicate **that his bowl of food is empty**.

But before we can decide this, there is still more we need to know about what Fido is trying to do. More specifically, is Fido trying through his action to influence his master's beliefs or actions? Is Fido trying to get his master to believe something, or is he trying to get him to do something? To try to influence a person's beliefs requires, it seems, some awareness that that person has beliefs that can be influenced. I think it is clear that this is something that humans do when they communicate with one another. But if one doubted that dogs and cats are aware of their own beliefs and desires, then one would likely doubt that they are aware that people have beliefs and desires. Still, we sometimes communicate with others with the intention of influencing their actions, as when we give

warnings or orders. But perhaps we do this with the primary intention of influencing their beliefs, hoping that this will lead to the desired action. What is clear, in any event, is that we humans often do communicate with the intent of influencing the beliefs and desires of other people, whether or not this intention is required for genuine communication.

It is also clear that, whether it is necessary or not, acting with an intention to influence someone's beliefs is not enough for genuine communication. I might leave the milk carton on the counter, intending that when my wife notices that it is empty she will plan to buy one on her way home. If my plan succeeds, I will have influenced her beliefs. But it seems wrong to say that I would have communicated to her that the milk carton is empty, or that we need more milk, even though I deliberately caused her to believe these things. If, instead, I had made a show of holding the carton upside down in her presence I might well have communicated these things to her. But what is the relevant difference? Part of the difference, in this example anyway, is that in the second case my wife would know that I am trying to influence her beliefs. She would recognize that in making a show of holding the carton upside down I was trying to make her see that the milk is gone (or that I believe that it is gone). Genuine communication, it seems, may require that the audience recognize one's intention to influence his or her beliefs or actions.

This gives rise to a possible asymmetry in the case of dog-human communication. Plausibly, in knocking his food bowl around, Fido is intending to show his master that the bowl is empty, and no doubt his master can recognize this intention. This could be so even if Fido himself is not aware of having this intention or of his master's recognizing it. And of course the master can act with the intention of influencing Fido's beliefs or actions. But can Fido, or any dog, recognize such an intention in his master? Can Fido figure out that when his master pulls back on the leash he or she is trying to get Fido to heel? Again, if one doubts that dogs and cats are aware of their own beliefs and intentions then one might well doubt whether they are aware of the beliefs and intentions of others. And if they cannot recognize intentions and beliefs in others, and if this recognition is needed for the audience in genuine communication, then dogs and cats cannot be the audience of genuine communication. But so long as trying to communicate does not itself require being aware of intentions, then dogs and cats might be able to communicate, even if they are incapable of being the audience of a communication. This is the potential asymmetry.

One might think – perhaps with some justification – that the question of whether Fido is communicating

or not is, at this point in the discussion, more than a little terminological. After all, all sides can agree – supposing certain empirical questions about the self-awareness of dogs and cats to have been settled – about what dogs and cats and humans can and cannot do to try to influence beliefs and actions. Deciding whether to call what nonhuman animals do ‘communication’ may seem less important than recognizing the differences and similarities between what all sides agree that human and nonhuman animals can do. In any event, progress in understanding animal communication requires further empirical study, not terminological decision.

The discussion until now has left language out of the picture. The examples have all been of nonlinguistic communication. It is undeniable that we do communicate nonlinguistically with others using waves, winks, and kicks under the table (although there are terminological questions about just how to draw the line between linguistic and nonlinguistic communication). When we do so, we hope that our audience will be able to recognize our intention to communicate. There is nothing, I think, essentially new about linguistic communication except that it involves speech acts – acts done with words having a conventional meaning. However, reliance on conventions is not unique to linguistic communication, since nonlinguistic communication using signals and codes may also involve conventions. There is considerable current research about the nature or essence of human language and how it differs from codes or signal systems. Some leading philosophers also question whether human language is in any interesting sense meant for or designed for communication.

Some philosophers have argued, though, that nonlinguistic forms of communication are in a way dependent on linguistic forms. Some, such as René Descartes in the 17th century and Donald Davidson in the 20th century, held that genuine communication is essentially linguistic. With this view, having beliefs and intentions requires having language, and since (as we have seen) communication requires having beliefs and intentions, communication requires having language. Since dogs and cats have no beliefs they are, on this view, incapable of communication. This is, however, a minority opinion.

The rough definition of communication I have sketched applies just as much to linguistic communication as to nonlinguistic communication. To communicate is to perform an action, perhaps a speech act, with the intention of influencing an audience’s beliefs or actions and whose success requires that the audience recognize this intention. This is just a rough sketch of a complete picture. Considerable ongoing philosophical research is aimed at filling in

the details. In particular, research is focused on the precise nature of the relevant intentions.

Interpretation and Understanding

Communication, whatever it is, succeeds only when the audience correctly understands the communicator, when he or she correctly interprets what the communicator intended him or her to come to believe or do. Philosophers have asked various epistemological questions about the extent to which we can and do understand each other. Some are quite skeptical that communication ever succeeds.

One kind of philosophical question concerns the possibility that some of an agent’s thoughts are essentially private, in the sense that only that agent can think them. Such thoughts would be essentially incommunicable, ones an agent could never communicate to anyone else. One purported kind of example includes thoughts about the character of an agent’s own conscious experience. If no one else can know what it is like for me to taste chocolate or to see red, perhaps no one else can truly understand what I say when I try to describe these experiences. Perhaps what it is like to be me, from the inside, is something I can never fully communicate with another. A related kind of purportedly private thoughts are so-called first-person thoughts: thoughts an agent has about her own place in the world. Perhaps what I think when I think that I am in Buffalo is not what you (or I) think when you (or I) think that David Hunter is in Buffalo. Perhaps thoughts that locate my own position for me are not thoughts that others can share. If some thoughts are private in this way, then they would mark one principled limit to communication. But what such private thoughts might be like – and indeed whether they are even possible – are areas of ongoing philosophical research.

A more generalized skepticism about communication derives from the fact that what a person means by his or her words can never neatly be separated from what he or she believes. We use our words to express our beliefs, but what we intend to say depends on what we believe our words can be used to say. So we cannot understand what someone is saying without knowing what they believe, but our best insight into what they believe is through our understanding of what they say. This fact about the interdependence of meaning and belief has led some philosophers to suggest that what a person means depends on their entire cultural milieu. Different cultures, according to this position, have different systems of belief, or different worldviews, and interpreting or understanding an agent from another culture requires sharing or at least knowing that worldview.

A related position is that scientists working within different scientific paradigms, such as pre- and post-Einsteinian physics, cannot genuinely understand each other, because the meanings of their shared words derive from different theoretical structures. It is not just that what Newton meant by 'energy' is not what Einstein meant by it. Rather, the claim is, Einstein could not even understand what Newton meant by it, since he did not share Newton's scientific paradigm.

This skepticism conflicts with the apparent ease of cross-cultural communication and ordinary interpretation. Perhaps this skepticism rests on mistaken semantic assumptions. But it may be that the appearance of easy communication stems from the fact that we typically assume that other people generally share our beliefs and meanings. Perhaps this 'principle of charity' in interpretation creates an illusion of successful communication. In any event, the general point that there is some interdependence between what a person means by their words and what they believe can hardly be doubted and is enough to raise some doubt about just how successful ordinary communication really is.

A more severe skeptical worry starts from the fact that any theory is under-determined by evidence. It is a general fact about the nature of theories that very different, even conflicting, accounts of some phenomena will be compatible with all the available evidence. In the case of communication, this means that very different interpretations of someone's speech act will make equally good sense of all available (indeed, of all possible) evidence. Just as a scientific theory can be adjusted in countless ways to accommodate new evidence, so our interpretation of a speech act can be varied in countless ways by varying our interpretation of the agent's beliefs or meanings. By itself, this under-determination suggests that we might never be in a position to know that our interpretations are correct, since no amount of evidence could identify a single best interpretation. Meaning might forever transcend our ability to know. Some doubt whether this brand of skepticism constitutes a special problem for communication, since all of our theories are under-determined by evidence. Perhaps if our epistemic position with respect to meaning is no worse than that with respect to, say, atomic physics, then we can live with this much skepticism about interpretation.

However, the American philosopher W. V. O. Quine argued powerfully that there is a special problem in the case of communication. In early work, he stressed the idea that the under-determination of translation would occur, even if there were no under-determination of physics. Even if we agreed on all the physical facts, we might not, he argued, be able to agree on a

unique best interpretation of an agent's speech act, since there would still be room to vary the agent's beliefs and desires. The physical facts, in his view, do not determine the semantic ones. In later work, Quine stressed the idea that in the case of, say, physics, we are prepared to admit that the physical facts might transcend our cognitive capacities. We might, he held, simply lack the intellectual resources needed to discover those facts, since nothing in the facts themselves guarantees that we can know them. As a result, he said, we are prepared to say that even though conflicting physical theories might be equally compatible with all available evidence, at most one of them can be true. This means that we might not be able to tell which theory is true. However, Quine argued, it makes no sense to suppose that what someone means by his or her words or what he or she believes could transcend the evidence we have at our disposal. Facts about meaning and belief are, he held, essentially public and knowable by us. So, he concluded, the special problem for interpretation and understanding is that it makes no sense to say that one interpretation is truer than any other, so long as they each make equally good sense of the evidence. It is not that facts about meaning could go beyond what we can know; it is that there is nothing more to meaning than what we can know. And because what we can know fails to determine a unique translation, this means that translation is indeterminate.

While Quine's writings on this topic have been extremely influential, there is little consensus about just what his arguments are, let alone what the consequences of his view would be. And while he has won few converts, there is no consensus about where his arguments go wrong. Some have responded that Quine unjustly adopted behaviorist limits on the available evidence or that he overlooked other sources of evidence at our disposal. Still, the thesis of the indeterminacy of translation is one of the most significant contributions to the philosophy of communication of the 20th century.

Comparatives: Semantics

C Kennedy, Northwestern University, Evanston, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The ability to establish orderings among objects and make comparisons between them according to the amount or degree to which they possess some property is a basic component of human cognition. Natural languages reflect this fact: all languages have syntactic categories that express gradable concepts, and all languages have designated comparative constructions, which are used to express explicit orderings between two objects with respect to the degree or amount to which they possess some property (Sapir, 1944).

In many languages, comparatives are based on specialized morphology and syntax. English exemplifies this type of system. It uses the morphemes *more-er*, *less*, and *as* specifically for the purpose of establishing orderings of superiority, inferiority, and equality, respectively, and the morphemes *than* and *as* to mark the standard against which an object is compared:

- (1a) Mercury is closer to the sun than Venus.
- (1b) The Mars Pathfinder mission was less expensive than previous missions to Mars.
- (1c) Uranus doesn't have as many rings as Saturn.

In the case of properties for which specific measure units are defined, it is also possible to express differences between objects with respect to the degree to which they possess some property, even when the

predicate from which the comparative is formed does not permit explicit measurement:

- (2a) Mercury is 0.26 AU closer to the sun than Venus.
- (2b) ??Mercury is 0.46 AU close to the sun.

Languages such as English also allow for the possibility of expressing more complex comparisons by permitting a range of phrase types after *than* and *as*. For example, (3a) expresses a comparison between the degrees to which the same object possesses different properties, (3b) compares the degrees to which different objects possess different properties, and (3c) relates the actual degree that an object possesses a property to an expected degree.

- (3a) More meteorites vaporize in the atmosphere than fall to the ground.
- (3b) The crater was deeper than a 50-story building is tall.
- (3c) The flight to Jupiter did not take as long as we expected.

Finally, many languages also have related degree constructions that do not directly compare two objects but instead provide information about the degree to which an object possesses a gradable property by relating this degree to a standard based on some other property or relation. The English examples in (4) using the morphemes *too*, *enough* and *so* exemplify this sort of construction.

- (4a) The equipment is too old to be of much use to us.
- (4b) Current spacecraft are not fast enough to reach the speed of light.

- (4c) The black hole at the center of the galaxy is so dense that nothing can escape the pull of its gravity, not even light.

Example (4b), for example, denies that the speed of current spacecraft is as great as the speed required to equal the speed of light.

Gradability

A discussion of the semantics of comparison must begin with the semantics of gradable predicates more generally. Not all properties can be used in comparatives, as shown by the contrast between the examples in (1) and (5).

- (5a) ??Giordano Bruno is deader than Galileo.
 (5b) ??The new spacecraft is more octagonal than the old one.
 (5c) ??Carter is as former a president as Ford.

The crucial difference between predicates such as *expensive* and *close*, on the one hand, and *dead*, *octagonal*, and *former*, on the other, is that the first, but not the second, are gradable – they express properties that support (nontrivial) orderings. Comparatives thus provide a test for determining whether a predicate is inherently gradable or not.

The most common analysis of gradable predicates assigns them a unique semantic type that directly represents their order-inducing feature; they are analyzed as expressions that map their arguments onto abstract representations of measurement, or scales. Scales have three crucial parameters, the values of which must be specified in the lexical entry of particular gradable predicates: a set of degrees, which represent measurement values; a dimension, which indicates the property being measured (cost, temperature, speed, volume, height, etc.); and an ordering relation on the set of degrees, which distinguishes between predicates that describe increasing properties (e.g., tall) and those that describe decreasing properties (e.g., short) (see Sapir, 1944; Bartsch and Vennemann, 1973; Cresswell, 1977; Seuren, 1978; von Stechow, 1984a; Bierwisch, 1989; Klein, 1991; Kennedy, 1999; Schwarzschild and Wilkinson, 2002).

The standard implementation of this general view claims that gradable predicates have (at least) two arguments: an individual and a degree. Gradable predicates further contain as part of their meanings a measure function and a partial ordering relation such that the value of the measure function applied to the individual argument returns a degree on the relevant scale that is at least as great as the value of the degree argument. The adjective *expensive*, for example, expresses a relation between an object x and a degree of cost d such that the cost of x is at least as great as d .

In order to derive a property of individuals, it is necessary to first saturate the degree argument. In the case of

the positive (unmarked) form, the value of the degree argument is contextually fixed to an implicit norm or standard of comparison, whose value may vary depending on a number of different contextual factors (such as properties of the subject, the type of predicate, and so forth). For example, the truth conditions of a sentence such as (6a) can be represented as in (6b), where *size* is a function from objects to degrees of size and d_s is the contextually determined standard – the cutoff point for what counts as large in the context of utterance.

- (6a) Titan is large.
 (6b) $size(t) \geq d_s$

In the context here, the various objects in the solar system, the value of d_s is typically such that (6a) is false. If we are talking about Saturn's moons, however, then d_s is such that (6a) is true. This sort of variability is a defining feature of gradable adjectives as members of the larger class of vague predicates.

Comparison

In contrast to the positive form, comparatives (and degree constructions in general) explicitly fix the value of the degree argument of the predicate. There are a number of implementations of this basic idea (see von Stechow, 1984a, for a comprehensive survey), but most share the core assumption that the comparative morphemes fix the value of the degree argument of the comparative-marked predicate by requiring it to stand in a particular relation – $>$ for *more*, $<$ for *less*, and \geq for *as* – to a second degree, the comparative standard, which is provided by the comparative clause (the complement of *than* or *as*).

One common strategy is to assign the comparative morpheme essentially the same semantic type as a quantificational determiner – it denotes a relation between two sets of degrees. One of these sets is derived by abstracting over the degree argument of the comparative predicate; the second is derived by abstracting over the degree argument of a corresponding predicate in the comparative clause. This analysis presupposes that the comparative clause contains such a predicate. In some cases, it is present in the surface form (see (3b)), but typically, in particular whenever it is identical to the comparative predicate, it is eliminated from the surface form by an obligatory deletion operation.

For example, in the analysis developed in Heim (2000), *more (than)* denotes a relation between two sets of degrees such that the maximal element of the first (provided by the main clause) is ordered above the maximal element of the second (provided by the comparative clause). At the relevant level of semantic representation, a sentence such as (7) has the constituency indicated in (8a) (where material elided

from the surface form is struck through) and the truth conditions in (8b).

- (7) Titan is larger than Hyperion.
 (8a) [Titan is d large] more than [Hyperion]
 (8b) $\max\{d \mid \text{large}(t) \geq d\} > \max\{d' \mid \text{large}(h) \geq d'\}$

Note that because the truth conditions of the comparative form do not involve reference to a contextual norm, the comparative does not entail the corresponding positive. Thus (8a), for example, can be true even in a context in which (6a) is false.

Differential comparatives such as (2a) can be accounted for by modifying the basic semantics to include a measure of the difference between the respective (maximal) degrees contributed by the two arguments of the comparative morpheme (von Stechow, 1984a; Schwarzschild and Wilkinson, 2002). Such differences always correspond to closed intervals on a scale and so are measurable even if the degrees introduced by the base-gradable predicate themselves are not (Seuren, 1978; von Stechow, 1984b; Kennedy, 2001).

Because the standard of comparison is derived by abstracting over a degree variable in the comparative clause, this approach allows for the expression of arbitrarily complex comparisons such as those in (3). There are some limits, however. First, the comparative clause is a *wh*-construction, so the syntactic operation that builds the abstraction structure is constrained by the principles governing long-distance dependencies (see Kennedy, 2002, for an overview). Second, it is also constrained by its semantics; because the comparative clause is the argument of a maximalization operator, it must introduce a set of degrees that has a maximal element. Among other things, this correctly predicts that negation (and other decreasing operators) are excluded from the comparative clause (von Stechow, 1984a; Rullmann, 1995):

- (9a) ??Venus is brighter than Mars isn't.
 (9b) $\max\{d \mid \text{bright}(v) \geq d\} > \max\{d' \mid \neg \text{bright}(m) \geq d'\}$

The set of degrees d' such that Mars is not as bright as d' includes all the degrees of brightness greater than the one that represents Mars's brightness. Because this set has no maximal element, the maximality operator in (9b) fails to return a value.

The hypothesis that the comparative clause is subject to a maximalization operation has an additional logical consequence (von Stechow, 1984a; Klein, 1991; Rullmann, 1995); for any (ordered) set of degrees D and D' , if $D \subseteq D'$, then $\max(D') \geq \max(D)$. The comparative clause is thus a downward-entailing context and so is correctly predicted to license negative-polarity items and conjunctive interpretations of

negation (Seuren, 1973; Hoeksema, 1984; but cf. Schwarzschild and Wilkinson, 2002):

- (10a) The ozone layer is thinner today than it has ever been before.
 (10b) We observed more sunspot activity in the last 10 days than anyone has observed in years.
 (11a) Jupiter is larger than Saturn or Uranus. \Rightarrow
 (11b) Jupiter is larger than Saturn, and Jupiter is larger than Uranus.

Finally, the assumption that the comparative is a type of quantificational expression leads to the expectation that it should participate in scopal interactions with other logical operators. The ambiguity of (12), which has the (sensible) *de re* interpretation in (13a) and an (unlikely) *de dicto* interpretation in (13b), bears out this prediction.

- (12) Kim thinks Earth is larger than it is.
 (13a) $\max\{d \mid \text{think}(\text{large}(e) \geq d) (k)\} > \max\{d' \mid \text{large}(e) > d'\}$
 (13b) $\text{think}(\max\{d \mid \text{large}(e) \geq d\}) > \max\{d' \mid \text{large}(e) > d'\} (k)$

The extent to which comparatives interact with other operators and the implications of such interactions for the compositional semantics of comparatives and gradable predicates is a focus of current investigation (see Larson, 1988; Kennedy, 1999; Heim, 2000; Bhatt and Pancheva, 2004).

Comparison Cross-Linguistically

As previously noted, there are in fact several distinct semantic analyses of comparatives that differ in their details but share the core assumption that gradable adjectives map objects to ordered sets of degrees. For example, one alternative analyzes the truth conditions of a sentence such (7) as in (14); roughly, there is a degree d such that Titan is at least as large as d but Hyperion is not as large as d (Seuren, 1973; Klein, 1980; Larson, 1988).

- (14) $\exists d[(\text{large}(t) \geq d) \wedge \neg(\text{large}(h) \geq d)]$

Analysis (14) does not express an explicit ordering between two degrees but instead takes advantage of the implicit ordering on the scale of the predicate to derive truth conditions equivalent to (8b) – given the inherent ordering, (14) holds whenever the maximal degree of Titan's largeness exceeds that of Hyperion (and vice versa).

The fact that the underlying semantics of gradable predicates supports multiple equivalent logical analyses of comparatives appears at first to be a frustrating obstacle to the discovery of the 'right' semantics of the comparative. In fact, however, this

may be a positive result when we take into account the extremely varied syntactic modes of expressing comparison in the world's languages (see Stassen, 1985), which include forms that superficially resemble the logical representation in (14), such as the example from Hixkaryána in (15).

- (15) Kaw-ohra naha Waraka, kaw naha Kaywerye
tall-NOT he-is Waraka tall he-is Kaywerye
'Kaywerye is taller than Waraka'

Although it may turn out to be difficult to find clear empirical evidence to choose between competing, equivalent logical representations of comparatives within a particular language such as English, it may also turn out that a study of the various expressions of comparison in different languages will show that all the possible options provided by the underlying semantics of gradability are in fact attested. Comparatives, therefore, provide a potentially fruitful and important empirical domain for investigating broader typological questions about the mapping between (universal) semantic categories and (language-specific) syntactic ones.

Compositionality: Philosophical Aspects

F J Pelletier, Simon Fraser University,
Burnaby, BC, Canada

© 2006 Elsevier Ltd. All rights reserved.

There are three different but loosely related conceptions that are associated with the term 'compositionality' in the literature of philosophical and linguistic semantics.

One conception, taking its lead from the more literal sense of this technical term, concerns the manner of composition of objects in the world. In this sense, an object or type of object is compositional if it is identical with its parts when they are assembled in some specified way. A slogan for this notion of compositionality is: "An object is the sum of its parts." However, this is a slightly misleading slogan, because

it does not distinguish between two different types of objects made of the same parts but put together differently. This notion of compositionality is meta-physical in nature: it provides a characterization of the ontology of objects in the world, saying that they can all be described in terms of some basic atomic elements and their combinations. Along with this ontological feature often goes an epistemological feature: that one can know objects in the world by understanding what the atomic items are and the ways they can be assembled. Both the ontological and the epistemological aspects here are further associated with reductionism: the view that objects are “nothing more than” their parts. In this meaning of compositionality, the compositionists are often called ‘atomists,’ and anti-compositionists are called ‘holists’ or sometimes ‘wholists.’ These latter theorists deny that all objects can be described and known in terms of their parts and the arrangement of the parts – for instance, they might deny that a corporation, a nation, or a group is “nothing more than” the class of individuals making them up together with their relationships – and hence they are antireductionistic. They might also hold that there are emergent properties and gestalt properties that cannot be described and known in the way required by atomism. A slogan for these theories is: “The whole is more than the sum of its parts.”

In the field of semantics, whether semantics of natural language or of mental items, there is a somewhat different conception of compositionality in play. In this realm, it is meaning that is claimed to be compositional; but since meaning is always meaning of something, it is this other something that defines the parts and the whole, unlike the case of the first sort of compositionality. The slogan for this second conception of compositionality is: “The meaning of a whole is determined by the meaning of its parts and the way these parts are combined.” What we see here is that a **feature** of a whole (its meaning) is claimed to be **determined** by the similar feature in the parts of the whole, plus the mode of combination of these parts – unlike the case of the first type of compositionality, in which it was the whole itself that was alleged to be “nothing more than” its parts. In the second type of compositionality, the notions of ‘part’ and ‘whole’, as well as their mode of combination, are presupposed to be already defined in terms of an independent syntax (in the case of language) or an independent mental economy (in the case of concepts). So the realm of syntax or mental economy is presupposed to be compositional in the first sense, and the issue is whether the property of meaning that is associated with the parts and wholes will likewise compose. Since the second conception assumes that

the first conception applies to the background syntax, this second conception presupposes basic or primitive meanings for the atomic (syntactic or mental) parts out of which all other (syntactic or mental) items are composed. (Once this second notion of compositionality is acknowledged, where there is a presupposed part-whole structure and it is then asked whether a feature of the whole is somehow determined by the similar features in the parts, one can see questions of compositionality arising in many fields, not just in semantics. For example, one might wonder whether the intrinsic value of an action is determined by the values of the parts of the action and the way the parts are ordered. One might wonder whether the beauty of a whole is determined by the beauty of its parts and the way the parts are combined. One might wonder whether the duties and obligations of a corporation or a society are determined by those of its members and the way these members fit together to form the corporation or society.)

Obviously, whether semantic compositionality is true or false depends upon the presupposed syntax or mental economy, the conception of meaning under consideration, and what is meant by the phrase “is determined by.” Indeed, many theorists have thought that this indeterminism inherent in semantic compositionality shows that its truth or falsity is merely “a methodological matter.” For a small alteration in the underlying syntax or mental economy might make a given semantics become non-compositional; a slight change in the assumed notion of ‘determination’ might make it become compositional again; an inclusion or exclusion of some property as “being semantic meaning” (as opposed, say, to “being pragmatics”) makes it become non-compositional again; and there might be no reason to make these changes other than to keep or deny compositionality.

The most popular explanation of “is determined by” in the semantic compositionist’s slogan is that it means ‘is a (mathematical) function of’; so the slogan becomes: “The meaning of a complex syntactic unit is a (mathematical) function of the meanings of its syntactic parts and the way in which they are syntactically combined.” But according to some, this notion allows too much: it is claimed that if no constraints are put upon the function, nearly any meanings of parts and syntactic combination can be compositionally related to the meaning of a whole. Some theorists would want to make the function be natural or systematic (and so on), without saying much about what, exactly and in the abstract, would make a function be natural or systematic. More usual is to be given examples of what sort of mathematical function should be ruled out. Consider the idea that an adjective like *red* means something

different depending on what noun it modifies. For example, according to this view, *red wine* vs. *red rose* vs. *red hair* vs. *red skin* vs. *red grapefruit* all employ a different meaning of *red*. And then compositionality is false, because these phrases are all constructed by the same syntactic rule and yet the meaning of *red* changes as a result of some syntactic item (viz., the noun being modified) that is not a part of the lexical item *red*. But a defender of compositionality could respond that the meaning of *red* is constant throughout, by being disjunctive (“when modifying *wine* it means r_1 ; when modifying *hair* it means r_2 ; etc.”). This is a perfectly good mathematical function and would obviously yield the right meanings of wholes if there were enough disjuncts. Those who object to the mathematical notion of function in the definition of compositionality might claim here that disjunctive functions are “not natural.”

The notion opposed to semantic compositionality is ‘semantic holism’. However, this notion means different things to different theorists, and it is not always just taken to mean merely that there is no mathematical function that will generate the required meanings. For example, some people call semantic holism the view that “words have meaning only in the context of a sentence” or that no word or other syntactic unit (including sentences, paragraphs, and discourses) has meaning in itself, but only in the setting of an entire theory or worldview or form of life. Others take semantic holism to be that the meaning of a syntactically defined item is determined not only by the meanings of its syntactic parts and their syntactic combination but also by the nonlinguistic context in which the utterance is made. (For example, it might be thought that the meaning of *There is no money* depends on who is speaking, whether the audience knows which business deal is being discussed, and so forth.) And still other holists, not necessarily wanting to bring these nonlinguistic items into meaning, nonetheless might hold that there are cases where the meaning of a syntactically complex item depends on meanings of linguistic items that are not syntactic parts of the complex. (For example, in *The first man landed on the moon in 1969*, we cannot take the meaning of *the first man* and combine it with *landed on the moon in 1969* to get the right meaning, for there is no sense in which the sentence really is talking about *the first man*. Rather, the relevant meaning of the subject term is that of *the first man who landed on the moon*. But to obtain that meaning, we need to get information from the verb phrase. Hence, to get the meaning of the subject term we need information of items that are not syntactic parts of the subject term.)

A third conception for (semantic) compositionality is less definite than the preceding, and comes through

considerations that might be called ‘the magic of language’. A set of closely related considerations have been pointed at in various times in the history of philosophy, both Western and Indian:

- We can **understand** an infinite number of novel sentences, so long as they employ words we already understand. We understand sentences and combinations that we have never encountered.
- We can **create** new sentences that we have never heard or used before, and we know that they are appropriate to the situation in which we use them.
- We are finite creatures who are exposed to a finite amount of information concerning our language. Nonetheless, we **learn** a system that is capable of infinite expression.

These considerations all point to the same features: (1) that language is something special (infinite, novel, creative, or whatever) and (2) that people manage to use/learn/understand language despite their finite nature. It is natural to see compositionality as an explanation of this ability – people have a finite stock of atomic items whose meanings are learned primitively, and there is a finite number of rules of combination whose effect on meaning are learned. But given that the rules are recursive in nature, this allows for an infinite number of sentences whose meanings are finitely knowable. (The opening paragraph of Frege [1923] is often taken to be an endorsement of this argument for compositionality, but it is a matter of scholarly dispute as to whether or not Frege actually believed in semantic compositionality. See Pelletier, 2001 and Janssen, 2001 for discussion and further references.)

This third conception of (semantic) compositionality is a ‘functional’ one and thus less definite than the preceding two. It amounts to saying that compositionality is *whatever* accounts for the magic of language. It might be the second conception of compositionality, with its mathematical functions, that will do the trick, or it might be some other, more exotic type of function. Or it may be some function that operates on items that are not necessarily syntactic subparts of the expression to be evaluated, and somehow thereby brings in information from context (of both linguistic and nonlinguistic varieties).

The magic of language considerations are the only arguments in favor of compositionality that do not seem merely to turn on such methodological considerations as the aesthetics of the syntax-semantics interface. However, it should be noted that they are not conclusive in relation to compositionality-as-mathematical-function. The second notion of compositionality does not guarantee the magic, nor does

non-compositionality in this second notion necessarily deny the magic. For it might be that the meaning of every syntactic whole is a function of the meanings of its parts and its syntactic mode of combination, but if these functions are not computable functions, then the language cannot be learned/used/understood in the way required by the magic. On the other hand, even if there is no function defined solely by the meanings of the parts and their modes of combination that will yield the meanings of the wholes, it could nonetheless be true that these meanings are computable in some other way ... and then the magic would still be there. (An example of this possibility is Pelletier's 1994/2004 'semantic groundedness'.)

Considerations Against Semantic Compositionality

The linguistic semantics literature is rife with demonstrations of how some linguistic phenomenon can or cannot be given a compositional description. It often seems that these works would more accurately be described as demonstrating how a phenomenon can or cannot be given a compositional description **employing some particular syntactic-semantic device or within some specific syntactic-semantic theory**. There are, however, three more general arguments that have been presented against semantic compositionality. The first is an argument from (nonlinguistic) context, of the sort mentioned above, where it is claimed that the meaning of a sentence in a context just cannot be derived from the meanings of the words and their combinations. In evaluating this argument, scholars need to distinguish between (what might be called) 'literal meaning' and 'occasion meaning'. The former is thought of as the meaning-in-language, while the latter is thought of as the meaning-in-a-context. If there is such a distinction, then there will be two principles of semantic compositionality – one for each type of meaning. And it is not so clear that either of them is overturned by considerations of context. The only casualty would be a mixed principle that no one believes, i.e., that the occasion meaning of a complex expression is a mathematical function of the literal meanings of its parts and their manner of combination.

The second general argument against compositionality comes from the existence of synonymy and Mates-like (Mates, 1950) considerations. Given that there is synonymy, so that x_1 and x_2 mean the same, then there are two sentences, S_1 and S_2 , that differ only in that one contains x_1 while the other contains x_2 . Given compositionality, it follows that S_1 and S_2 are synonymous too; and by compositionality again, it follows that *Mary believes S_1* and *Mary believes S_2*

are synonymous. But for any such S_1 and S_2 , it can be the case that the former is true, while the latter is false. However, it cannot be the case that, of two synonymous sentences, one is true and the other false. Hence, either there is no synonymy or else compositionality is wrong. And the existence of synonymy is more secure than that of compositionality.

The third general argument comes from the existence of ambiguity. If compositionality implies that the meaning of a whole is a mathematical function of the meanings of its parts (and combination), then there cannot be any ambiguity of the sort where **one and the same item** has two or more meanings, for that would deny that it was a function that computed meaning. As with synonymy, one could of course deny the existence of ambiguity; but most theorists find that this is too lavish a position to take. So it is usually admitted by compositionlists that individual words can be ambiguous; therefore, sentences using these ambiguous words may also be ambiguous (but the ambiguities are always traceable to the ambiguity of the words). Also, it is pointed out that strings of words such as *Visiting professors can be fun* are ambiguous (is it the professors or the activity of visiting the professors that can be fun?), but this ambiguity is traceable to the fact that the words are put together in different ways – that is, there are different structural descriptions that can be associated with this string of words. Hence, this ambiguity is not a challenge to compositionality. However, Pelletier (1994/2004) points to a number of examples that seem neither to have ambiguous words nor to have different structural descriptions but which are nonetheless ambiguous. For example: *When Alice rode a bicycle, she went to school*. This seems to have but one syntactic analysis within any particular theory, but its meaning is ambiguous: *On those occasions where Alice rode a bicycle, she took it to school* vs. *Back in the days when Alice was a bicyclist, she was a student*.

Formal Considerations

There have been a number of works concerned with the question of whether compositionality is a nonempirical issue on the grounds of certain formal features that are required by compositionality. A review article that surveys this work is Westerståhl (1998). More recent work on formal features of compositional semantics is in the important work of Hodges (2001) and material based on this.

History

Although the general principle of compositionality seems to have been around for some time, as mentioned earlier, it is not clear when the term

'compositionality' came into the linguistic semantics literature (unlike 'holism,' which was introduced by Smuts, 1926). 'Compositionality' is used by Katz (1973) and Thomason (1974).

Compositionality: Semantic Aspects

G Sandu and P Salo, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

According to the principle of compositionality, the meaning of a complex expression depends only on the meanings of its constituents and on the way these constituents have been put together. The kind of dependence involved here is usually a functional one.

Principle of Compositionality (PC): The meaning of complex expression is a function of the meanings of its constituents and of the rule by which they were combined.

PC is rather vague unless one specifies the meanings of 'is a function of' and 'meaning(s)', something that is easier said than done. A more rigorous formulation

of these notions is possible for formal languages and is due to Richard Montague.

Montague (1974) defined compositionality as the requirement of the existence of a homomorphism between syntax and semantics, both to be understood as 'structures' in the mathematical sense. To keep technicalities down to a minimum, Montague's requirement of a compositional interpretation was that for each syntactic operation 'O' that applies to n expressions e_1, \dots, e_n in order to form the complex expression ' $O(e_1, \dots, e_n)$ ', the interpretation of the complex expression ' $O_i(e_1, \dots, e_n)$ ' is the result of the application of the semantic operation ' C_i ', which is the interpretation of ' O_i ' to the interpretations m_1, \dots, m_n of ' e_1, \dots, e_n ', respectively. In other words, the interpretation of ' $O_i(e_1, \dots, e_n)$ ' is $C_i(m_1, \dots, m_n)$.

An immediate consequence of PC is the ‘Substitutivity Condition’: Substituting a constituent with its synonym in a given expression does not change the meaning of the resulting expression. Thus, PC is violated if a complex expression has meaning but some of its component expressions do not (the Domain Condition) or if the Substitutivity Condition fails.

As one can see, PC is by itself rather weak, and so it comes as no surprise that in the case of formal languages, one can always devise a trivial compositional interpretation by assigning some arbitrary entities to the primitive expressions of the language and then associating arbitrarily the syntactic operations of the language with corresponding operations on the domain of those entities. This way of implementing the principle can hardly be of any interest, although it has led some philosophers and logicians to claim that PC is methodologically empty.

A slightly more interesting case is the one in which one has an intended semantic interpretation in mind, that is, an interpretation with an intended domain of entities for the primitive expressions of the language to be mapped into, and a class of intended operations to serve as the appropriate interpretations of the syntactic operations of the language. A case in point is Horwich’s (1998) interpretation. His formal language was intended to serve as a regimentation for a fragment of English that contains proper names (‘John,’ ‘Peter,’ etc.), common nouns (‘dogs,’ ‘cows,’ etc.), and verb phrases (‘talks,’ ‘walks,’ ‘bark,’ etc.) as primitive expressions together with grammatical operations on them. For simplicity, let us assume predication is such a grammatical operation marked in this case by an empty space. Thus the syntax contains clauses of the form:

If ‘*n*’ is a proper name and ‘*v*’ is a verb phrase, then ‘*n v*’ is a complex expression.

The intended semantic interpretation consists of a domain of entities that serve as the intended meanings of the proper names and verbs phrases (whatever they are; they are marked by capitals), together with an operation – say, *P* – that interprets the grammatical operation of predication (whatever that is). The only thing one needs to worry about in this case is to see to it that the operation of predication is defined for the entities mentioned above. The relevant semantic clauses now have this form:

The interpretation of ‘*n v*’ is the result of the application of *P* to the entities assigned to ‘*n*’ and ‘*v*’, respectively.

Thus, the interpretation of the sentence ‘John talks’ is the result of the application of *P* to TALKS to JOHN. This interpretation is trivially compositional in that the interpretation of every compound ‘*n v*’ has been defined as the result of the application of the

operation assigned to the syntactic operation of concatenation to the interpretations of ‘*n*’ and ‘*v*’, respectively. The more challenging cases for PC are those in which one has an intended interpretation for the complex expressions and would like to find a compositional interpretation that agrees with it. In contrast to the previous case, the meanings of the complex entities are not any longer defined but are given at the outset. We have here a typical combination of PC with the *Context Principle* (CP): An expression has a meaning only in the context in which it occurs. The combination was largely explored in the work of Gottlob Frege and in Donald Davidson’s theory of meaning, which assumed the form of a theory of truth. Davidson took whole sentences to be the meaning-carrying units in language, and truth to be a primitive, undefinable semantic property that is best understood. Truth being undefinable, the strategy applied above, which ensured a trivial implementation of PC, is no longer available. Instead, PC acquires the status of a methodological constraint on an empirical theory of truth for the target language: the division of a sentence into parts and their association with appropriate semantic entities in a compositional theory becomes a theoretical business that has no other role except to show how they contribute to the computation of the truth of the sentences of the target language in which they occur.

The literature on formal semantics for natural language has plenty of cases of the application of the Context Principle. We consider just two examples. In *game-theoretical semantics* (GTS), one starts with a standard first-order language and defines truth only for the sentences of that language. The truth of every such sentence (in a prenex normal form) is defined via a second-order sentence, known as its Skolem form. This interpretation is clearly not compositional, since it violates the Domain Condition. One can now ask whether there is a compositional interpretation that agrees with the given game-theoretical interpretation of sentences. It is known that the answer is positive, but only assuming certain nontrivial mathematical principles (the Axiom of Choice).

The second example concerns Dynamic Predicate Logic. The starting point is the same language as in GTS – that is, a standard first-order language – but we now want a compositional interpretation in which, e.g., an existential quantifier occurring in the antecedent of a conditional binds a free variable occurring in the consequence of the conditional and in addition has the force of an universal quantifier. There is a compositional interpretation that has the required property, that of Dynamic Predicate Logic (Groenendijk and Stokhoff, 1991).

From a technical point of view, the situation described in the two examples may be depicted as an extension problem (Hodges, 1998). One starts with an intended interpretation *I*, which either (a) fixes only the interpretation of certain complex expressions (e.g., sentences) or (b) puts some relational constraints on the interpretation of complex expressions. One then wants to find a compositional interpretation *I'* that agrees with the independently understood interpretation *I*. Hodges's Extension Theorem solves case (a). It shows that any partial interpretation for a grammar can be extended to a total compositional interpretation. This shows that the combination of PC with CP (in its form [a]) is trivially satisfiable. The more interesting cases are those falling under (b). This is the situation that typically arises in the case of empirical linguistics where the intended interpretation is supposed to be motivated by empirical argument.

As an illustration, consider the much-discussed 'pet fish' problem. There is some empirical evidence to the effect that the meanings of concept words are prototypes. A prototype is either a good exemplar of the category or a statistical average of all or some instances of the category (Smith and Medin, 1981). A given instance *x* is then categorized as *X* if *x* resembles the prototype of *X* more than any other prototype. Given two expressions *X* (e.g., 'pet') and *Y* ('fish'), one asks whether there is an interpretation that assigns to the complex concept word *XY* ('pet fish') a prototype that is the composition of the prototype assigned to *X* and the prototype assigned to *Y*. One also wants the meaning function to satisfy certain basic properties that are required for explanatory purposes; e.g., it should be the case that if *x* is *XY*, it must also be *X* and *Y*. We thus want every *x* to resemble the prototype of *XY* no less than it resembles the prototypes of *X* and *Y*. It has been argued that there is no such interpretation, that is, there is no operation of composition that yields a prototype as the interpretation of *XY* with the desired properties when applied to the two prototypes that are the interpretations of *X* and *Y* respectively (Fodor, 1998; Osherson and Smith, 1981).

The moral to be drawn from all this should have been somehow anticipated from our discussion of formal languages. When the intended interpretation puts constraints only on the meanings of primitive expressions and on the operations governing them, PC follows rather trivially, provided the semantic entities of complex expressions are not constrained in any way.

When the intended interpretation concerns only the meanings of complex expressions, Hodges's extension theorem shows that a compositional semantics can still be found, at least in some cases, provided that one does not constrain the meanings of the primitive

expressions or syntactical operations on them. In natural language, however, the situation is hardly so simple, as one meets constraints at every level. It is no wonder, then, that Fodor and Lepore (2002) argued that most theories of concepts or mental architecture in cognitive science are in contradiction with PC. The case of prototype semantics was only one example, but the same considerations apply to the theory that the meaning of a word is its use or the criteria for its application, etc.

PC is often defended as the best explanation of the empirical phenomenon of systematicity: Any competent speaker of a given language who has in his repertoire the complex expressions *P*, *R*, and *Q* has also in his repertoire the complex expressions in which *P*, *R*, and *Q* are permuted (provided they are grammatical). For instance, anybody who understands the sentence 'Mary loves John' also understands the sentence 'John loves Mary'. Fodor and his collaborators argued extensively that PC is the best explanation of the systematicity of language, but this is an issue that will not be tackled here (cf. Fodor and Pylyshyn, 1988; Fodor, 2001; Fodor and Lepore, 2002; Fodor, 2003; Aizawa, 2002).

PC should not be confused with the principles of productivity or generativity of language, which require that the expressions of a language be generated from a finite set of basic expressions and syntactical rules. Although it presupposes that the language under interpretation has a certain syntactic structure, PC does not take a stand on how that structure should be specified (phrase structure rules, derivational histories, etc.), as long as it is given a compositional interpretation.

Concepts

E Margolis, Rice University, Houston, TX, USA

S Laurence, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

In cognitive science, concepts are generally understood to be structured mental representations with subpropositional content. The concept CHAIR, for example, is a mental representation with the content *chair*. It is implicated in thoughts about chairs and is accessed in categorization processes that function to determine whether something is a chair. Theories of concepts are directed to explaining, among other things, the character of these processes and the structure of the representations involved. Related to this is the project of explaining what conceptual content is and how concepts come to have their content. In the study of conceptual structure, four broad approaches should be distinguished: (1) the classical theory, (2) probabilistic theories, (3) the theory-theory, and (4) conceptual atomism. For recent overviews of theories of concepts, see Margolis and Laurence (1999) and Murphy (2002).

The Classical Theory

According to the classical theory, concepts have definitional structure. A concept's constituents encode conditions that are individually necessary and jointly sufficient for its application. A standard illustration of the theory is the concept BACHELOR, which is claimed to be composed of the representations UNMARRIED, ADULT, and MALE. Each of these is supposed to specify a condition that something must meet in order to be a bachelor and, if anything meets them all, it is a bachelor.

The classical theory has always been an enormously attractive theory. Many theorists find it to be intuitively plausible that our concepts are definable. In addition, the theory brings with it a natural and compelling model of how concepts are learned. They are learned by assembling them from their constituents. The classical theory also offers a straightforward account of categorization. Something is deemed to fall under a concept just in case it satisfies each and every condition that the concept's constituents encode. Finally, the theory appeals to the very same resources to explain the referential properties of a concept. A concept refers to those things that have each and every feature specified by its constituents. Of course, all of these explanations depend upon there being a separate treatment of the primitive (i.e., unstructured) representations that ultimately make up the concepts we possess. But the classical theory supposes that a separate treatment can be given, perhaps one that grounds all of our concepts in perceptual primitives in accordance with traditional empiricist models of the mind.

The classical theory has come under considerable pressure in the last thirty years or so. In philosophy, the classical theory has been subjected to a number of criticisms but perhaps the most fundamental is that attempts to provide definitions for concepts have had a poor track record. There are few – if any – examples of uncontroversial definitional analyses. The problem isn't just confined to philosophically interesting concepts (e.g., JUSTICE) but extends to concepts of the most ordinary kind, such as GAME, PAINT, and even BACHELOR (Wittgenstein, 1953; Fodor *et al.*, 1980). What's more, Quine's (1951) influential critique of the analytic-synthetic distinction has led

many philosophers to suppose that the problem with giving definitions is insurmountable.

For psychologists, the main objection to the classical theory has been that it appears to be at odds with what are known as ‘typicality effects.’ Typicality effects include a broad range of phenomena centered around the fact that certain exemplars are taken to be more representative or typical (Rosch and Mervis, 1975; Rosch, 1978). For instance, apples are judged to be more typical than plums with respect to the category of fruit, and subjects are quicker to judge that apples are a kind of fruit than to judge that plums are and make fewer errors in forming such judgments. Though not strictly inconsistent with these findings, the classical theory does nothing to explain them.

Probabilistic Theories

In response to the failings of the classical theory, Eleanor Rosch and others began exploring the possibility that concepts have a structure that is described as graded, probabilistic, or similarity-based (Smith and Medin, 1981). The difference between these approaches and the classical theory is that the constituents of a concept are no longer assumed to express features that its members have by definition. Instead, they are supposed to express features that its members tend to have. For example, a standard treatment for the concept BIRD incorporates constituents picking out the features *has wings*, *flies*, *eats worms*, etc., but probabilistic theories don’t require all of these features to be possessed by something to count as a bird. Instead, something falls under the concept when it satisfies a sufficient (weighted) number of them (or on some accounts, something falls under the concept to a degree corresponding to how many are satisfied; then nothing is a bird absolutely but only a bird to degree n).

Like the classical theory, probabilistic theories explain concept learning as a process where a concept is assembled from its constituents. And like the classical theory, probabilistic theories offer a unified treatment of reference and categorization. A concept refers to those things that satisfy enough of the features it encodes, and something is judged to fall under a concept when it satisfies enough of them as well. Categorization, on this account, is often described as a similarity comparison process. An item is categorized as belonging to a given category when the representations for each are deemed sufficiently similar, where this may be measured in terms of the number of constituents that they share.

One advantage of probabilistic theories is that a commitment to probabilistic structure may explain why definitions are so hard to come by. More important, however, is the way that probabilistic structure

readily accommodates and explains typicality effects. This is achieved by maintaining that typicality, like categorization, is a similarity comparison process. On this model, the reason apples are judged to be more typical than plums is that the concept APPLE shares more of its constituents with FRUIT. Likewise, this is why apples are judged to be a kind of fruit faster than plums are.

Probabilistic theories continue to enjoy widespread support in cognitive science, but they aren’t without their own problems. One concern is that many concepts appear to lack probabilistic structure, especially concepts that correspond to phrases as opposed to words. For example, Fodor (1981), (1998) notes that while GRANDMOTHER may have probabilistic structure (encoding the features *gray-haired*, *old*, *kind*, etc.), there is no such structure for GRANDMOTHERS MOST OF WHOSE GRANDCHILDREN ARE MARRIED TO DENTISTS. Fodor also challenges probabilistic theories on the grounds that even when phrasal concepts do have probabilistic structure, their structure doesn’t appear to be compositionally determined. This is a problem, since it’s the compositionality of the conceptual system that explains the productivity of thought, viz., the fact that there is no upper bound on the number of distinct thoughts that humans can entertain. Fodor points out that the probabilistic structure associated with PET FISH encodes features (*colorful*, *tiny*, *lives in a bowl*, etc.) that aren’t drawn from the probabilistic structures associated with PET (*furry*, *cuddly*, etc.) and FISH (*gray*, *lives in the ocean*, etc.).

Another common criticism of probabilistic theories is that they leave out too much. They don’t sufficiently incorporate the causal information that people appeal to in categorization and don’t do justice to the fact that reflective categorization isn’t always based on similarity (Murphy and Medin, 1985; Keil, 1989; Rips, 1989). For example, when time is short and when given little information about two animals apart from the fact that they look alike, people may judge that they are both members of the same category. But when asked for a more thoughtful answer about whether, for example, a dog that is surgically altered to look like a raccoon is a dog or a raccoon, the answer for most of us – and even for children – is that it remains a dog (see Gelman, 2003, for an overview of related literature).

The Theory-Theory

The theory-theory is largely a reaction to the last problem associated with probabilistic theories. It explains categorization, particularly reflective categorization, as a process of causal-explanatory reasoning. On this approach, conceptual structure is

a matter of how a concept is related to other concepts in relatively stable causal-explanatory frameworks. The designation ‘theory-theory’ sometimes implies little more than this. For some psychologists, it is meant to indicate that the explanatory frameworks are comparable to explicit scientific theories and that the mechanisms for acquiring them are identical with the cognitive mechanisms that underlie scientific reasoning. On this more extreme version of the theory-theory, conceptual development is likened to radical theory change in science (Carey, 1985; Gopnik and Meltzoff, 1997).

Many objections to the theory-theory are directed to its more extreme forms, particularly the commitment about conceptual development. The claim that infants are like little scientists has generated a great deal of criticism (e.g., Segal, 1996; Stich and Nichols, 1998). One objection focuses on particular examples, especially of concepts that are fundamental to human cognition (e.g., OBJECT, AGENT, and BELIEF). Although theory-theorists often cite these as examples where substantial conceptual change occurs – change that is supposed to illustrate the theory-theory’s model of cognitive development – others would argue that these are innate concepts that remain invariant in important respects throughout development (e.g., Leslie, 1994). A more basic objection to the theory-theory is that the appeal to causal-explanatory reasoning is minimally informative. It may be true that categorization is somewhat like scientific reasoning, but scientific reasoning is itself in need of a great deal of clarification. The result is that the model of categorization is extremely sketchy and somewhat mysterious.

A third objection to the theory-theory, one that has been especially influential in philosophy, is that it makes it difficult to maintain that different people have the same concepts. This objection is directed to versions of the theory-theory that are especially lenient in what counts as a theory. On these versions, just about any belief or inferential disposition associated with a concept is part of a ‘theory.’ The problem with this approach, however, is that people are bound to have different beliefs than one another and hence different theories. But since a concept’s identity and content are supposed to be a matter of its role in one’s mental theories, people will be unable to share concepts (Fodor and Lepore, 1992).

Conceptual Atomism

The last of the four theories of conceptual structure is that lexical concepts – word-sized concepts – have no structure at all (Fodor, 1998; Millikan, 2000).

Concepts such as BIRD, CHAIR, NUMBER, and RUN are all primitives. Of course, conceptual atomism needs an account of how these primitive concepts are to be distinguished from one another and how their contents are fixed. A standard approach is to appeal to the mind-world causal relations between a concept and the object or property it refers to.

Conceptual atomism is motivated in light of the problems with other theories, especially the problem of providing definitions (the classical theory), the problem of compositionality (probabilistic theories), and the problem of shared concepts (the theory-theory). If concepts lack structure, then it is no surprise that we have difficulty providing definitions for them. Also, it doesn’t matter that probabilistic structure doesn’t compose, since **complex** concepts can still be composed on the basis of atomic constituents. And sharing a concept is no longer a challenge. It isn’t a matter of having the same beliefs so much as having representations that stand in the same mind-world causal relations.

Conceptual atomism is sometimes rejected outright on the grounds that unstructured concepts can’t be learned and hence that atomism implies an untenably strong form of concept nativism (see **Innate Ideas**). The main concern with conceptual atomism, however, is that without structure, there is nothing to explain how concepts are implicated in categorization and other psychological processes. Nonetheless, atomists see this as an advantage rather than a problem, maintaining that people can have the same concept despite widely varying psychological dispositions. For this reason, the structures that are accessed in categorization and other psychological processes are said to be associated with a concept but not constitutive of it.

Conditionals

S Kaufmann, Northwestern University, Evanston, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Form and Meaning

Conditionals are complex sentences built up from two constituent clauses, called the *antecedent* and the *consequent*; alternatively, the terms *protasis* and *apodosis* are found in the linguistic literature. English conditionals are typically of the form *if A, (then) B*, where *A* and *B* are the antecedent and consequent, respectively. Some examples are given in (1).

- (1a) If the sun comes out, Sue will go on a hike.
- (1b) If the sun came out, Sue went on a hike.
- (1c) If the sun had come out, Sue would have gone on a hike.

In the linguistic and philosophical literature, a distinction is commonly drawn between *indicative* conditionals, such as (1a) and (1b), and *subjunctive* or *counterfactual* conditionals, like (1c). This classification is not uncontroversial: some authors would draw the major dividing line between (1a) and (1c) on the one hand and (1b) on the other. However, we

adopt the standard classification and focus on indicative conditionals (see also **Counterfactuals**). The class of indicatives may be further divided into *predictive* and *nonpredictive* conditionals, illustrated in (1a) and (1b), respectively. Despite subtle differences, these share a common semantic core and have similar logical properties. We do not distinguish between them in this discussion.

In general, *if A, B* asserts that *B* follows from, or is a consequence of *A*, without asserting either *A* or *B*. Often the relation in question is causal (*A* causes *B*) or inferential (*B* is inferable from *A*). Other uses include the statement that *B* is *relevant* if *A* is true (2a), conditional speech acts (2b), and metalinguistic comments on the consequent (2c).

- (2a) If you want to meet, I am in my office now.
- (2b) If you will be late, give me a call.
- (2c) If you excuse my saying so, she is downright incompetent.

The form *if A, B* is neither necessary nor sufficient for the expression of conditionality. Inverted forms, as in (3a), are used as conditional antecedents. Sentences like (3b) and (3c) also typically have conditional interpretations.

- (3a) Should the sun come out, Sue will go on a hike.
- (3b) Buy one – get one free.
- (3c) Give me \$10 and I will fix your bike.

On the other hand, some *if-then* sentences do not fit the semantic characterization and are not considered conditionals, as in (4).

- (4) If these problems are difficult, they are also fascinating.

Despite these marginal counterexamples, *if* is clearly the prototypical conditional marker in English. Other languages show more diversity in their expression of conditionality. The German conditional maker *falls* is freely interchangeable with *wenn* ‘when/if’, which also functions as a temporal conjunction. Japanese employs a family of verbal suffixes and particles (*-ba*, *-tara*, *-tewa*, *nara*, *to*), each of which adds subtle semantic and pragmatic constraints to the conditional meaning and some of which may also express temporal relations without conditionality (*-tara* ‘and then’; *A to B* ‘upon A, B’). Languages also vary in the extent to which they overtly mark (non)-counterfactuality. In Japanese, the distinction is usually inferred from context; Classical Greek, on the other hand, has an elaborate inventory of markers of different degrees of hypotheticality.

In all languages, the interpretation of conditionals is determined and constrained by expressions of temporal relations, modality, quantification, and a variety of pragmatic factors. For instance, the differences in (1a) through (1c) arise from the interaction of the marker *if* with the tenses and modal auxiliaries in the constituent clauses.

For descriptive surveys of conditionals in English and other languages, see Traugott *et al.* (1986), Athanasiadou and Dirven (1997), Dancygier (1998), and Declerck and Reed (2001).

Truth-Conditional Semantics

The formal semantic approach in linguistics and philosophical logic is concerned with the truth conditions of sentences and their logical behavior. Conditionals are among the most extensively studied linguistic constructions in this tradition and pose specific challenges, which have been addressed in a number of ways.

Material Conditional

In classical Fregean logic, *if A, B* is interpreted as the *material conditional* (also called material implication) ‘ \rightarrow ’:

- (5) $A \rightarrow B$ is true iff either A is false, or B is true, or both.

The material conditional is a truth function on a par with conjunction and disjunction. However, while there is general agreement that the latter are well suited to capture the truth conditions of *and* and *or*, the logical properties of the material conditional do not well match those of conditional sentences. For example, $A \rightarrow B$ and $A \rightarrow \neg B$ are mutually consistent, and the falsehood of A is sufficient for the truth of both, hence of their conjunction. But (6b) is intuitively contradictory and does not follow from (6a). Likewise, the negation of $A \rightarrow B$ is equivalent to $A \wedge \neg B$, but (6c) and (6d) are not intuitively equivalent.

- (6a) Today is Saturday.
- (6b) If today is Friday, it is raining, and if today is Friday, it is not raining.
- (6c) It is not the case that if the team wins, I will be happy.
- (6d) The team will win and I will be unhappy.

Strictly truth-functional theories employ the material conditional in spite of these shortcomings, since no other truth function comes any closer to capturing our intuitions about conditionals. One way to reconcile the approach with linguistic intuitions is to augment the truth conditions with pragmatic conditions on use. Jackson (1987), building on Grice’s original proposals, appealed to probabilistic ‘assertibility’ conditions. For *if A then B* to be assertible, two conditions must be met: $A \rightarrow B$ must be highly probable, and it must remain highly probable in the event that A turns out true. Jackson noted that this comes down to the requirement that the conditional probability of B given A be high.

(Variably) Strict Implication

An alternative reaction to the problems of the material conditional is to conclude that conditionals do not express truth functions. Instead, most current theories assume that *if A then B* asserts that A *cannot* be true without B also being true. This is typically spelled out in the framework of *possible worlds*:

- (7) *If A then B* is true at a possible world w relative to an accessibility relation R iff for all possible worlds w' such that wRw' and A is true at w' , B is true at w' .

The relation R determines the *modal base* (Kratzer, 1981), the set of possible worlds that are relevant to the truth of the conditional at w . Definition (7) subsumes the material conditional as the special case that R is the identity relation, so the only world

relevant at w is w itself. At the other end of the spectrum lies *strict implication*, under which *all* possible worlds are relevant and the conditional is true iff B is a logical consequence of A .

These extreme cases are rarely relevant in linguistic usage. Usually, conditionals are evaluated against speakers' beliefs, the conversational common ground, the information available in a given situation, possible future courses of events in branching time, or other background assumptions. All of these interpretations correspond formally to different choices of the accessibility relation. The fact that the intended reading need not be overtly marked is a source of versatility and context dependence. A given conditional can be simultaneously true with respect to one modal base and false with respect to another. Thus, (8) may be objectively true, but believed to be false by a speaker with insufficient information or false beliefs.

(8) If this material is heated to 500 °C, it will burn.

The definition in (7) makes room for variation and context dependence of the modal base and overcomes some of the limitations of the material conditional. However, like the latter, it fails to account for the invalidity of certain *nonmonotonic* inference patterns involving conditionals. For instance, under both analyses, a true conditional remains true under Strengthening of the Antecedent (*if A then B* entails *if C and A then B*). Intuitively, however, it is possible for (8) to be true while (9) is false.

(9) If this material is placed in a vacuum chamber and heated to 500 °C, it will burn.

There are several ways of addressing this problem. We will describe two of them, each departing from definition (7) in a different direction.

Relative Likelihood

The first approach takes examples (8) and (9) to show that in cases like (8), not all A -worlds in the modal base are relevant for the truth of the conditional, but only those that satisfy implicit defaults or 'normalcy' assumptions. The listener will assume that air was present (as in [8]) unless this is explicitly denied in the antecedent (as in [9]).

Kratzer (1981) represented such assumptions as an *ordering source*, a set of propositions that are 'normally' true at w . This set induces a preorder on the worlds in the modal base: w'' is at least as normal as w' iff all the propositions in the ordering source that are true at w' are also true at w'' . The interpretation of conditionals is sensitive to the relation in (10).

- (10) *If A then B* is true at w relative to a model base MB iff for every A -world w' in MB , there is an AB -world in MB that is at least as normal as w' and not equalled or outranked in normalcy by any A -world in MB at which B is false.

This offers a solution to the problem posed by (8) and (9). Suppose the material is normally not placed in a vacuum chamber. Then every antecedent-world at which it is, is outranked in normalcy by one at which it is not; thus, (8) may be true while (9) is false.

Formally, the order induced by the ordering source is similar to the relation of 'comparative similarity' between possible worlds that is at the center of the Stalnaker/Lewis theory of counterfactuals (*see* the article **Counterfactuals** for details; Lewis, 1981, for a comparison; and Stalnaker, 1975, for an account of indicative conditionals that refers to this notion). The term 'relative likelihood' is applied to such orders in artificial intelligence (Halpern, 2003). Like the modal base, the ordering source is subject to underspecification and context dependence. Different ordering sources correspond to different readings of the conditional. Besides normalcy, Kratzer (1981) considers ordering sources that rank worlds according to desires, obligations, and other criteria.

Probability

The second approach to dealing with the nonmonotonicity of conditionals does not manipulate the modal base but instead rejects the universal quantification over possible worlds as ill suited for modeling the notion of consequence that speakers employ in interpreting conditionals. On this account, *if A then B* asserts not that all A -worlds are B -worlds but rather that the conditional probability of B , given A , is high. In other words, the posterior probability of B upon learning A would be high, or, alternatively, a world that is randomly chosen from among the A -worlds would likely be one at which B is true. Different modal bases and ordering sources correspond to different (subjective or objective) probability distributions over possible worlds. Adams (1975) developed a theory of *probabilistic entailment* in which just those inference patterns that are problematic for the classical account, such as Strengthening of the Antecedent, are no longer predicted to be valid.

The intuitive appeal of the probabilistic approach is offset somewhat by the fact that it necessitates a rather profound rethinking of the logical basis of semantic theory. Lewis (1976) showed that a conditional probability cannot in general be interpreted as the probability that a proposition is true, hence that the central premise of the probabilistic account is at

odds with the idea that conditionals denote propositions (for detailed discussions see Edgington, 1995; Eells and Skyrms, 1994). Some authors conclude that conditionals do not have truth values (Adams, 1975) or that the conditional probability is only relevant to their use and independent of their truth conditions (Jackson, 1987). Another approach is to assign nonstandard truth values to conditionals in such a way that the problem is avoided (Jeffrey, 1991; Kaufmann, 2005).

Summary

Kratzer's theory is the most influential one in linguistics. The probabilistic approach has been studied extensively in philosophy and, more recently, artificial intelligence. Many other options have been explored. In addition to the works cited above, for overviews and specific proposals the reader is referred to Bennett (2003); Gärdenfors (1988); Harper and Hooker (1976); Harper *et al.* (1981); Jackson (1991); Nute (1980, 1984); Sanford (1989); Stalnaker (1984); Veltman (1985); and Woods (1997). It is not always clear whether there are empirical facts of a purely linguistic nature that would decisively favor one approach over another. With such criteria lacking, the choice depends on the purpose of the analysis at hand and other extralinguistic considerations (e.g., assumptions about rational behavior or psychological reality, or tractability in computational modeling).

Context and Common Ground

H H Clark, Stanford University, Stanford, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

People talking to each other take much for granted. They assume a common language. They assume shared knowledge of such things as cultural facts, news stories, and local geography. If they know each other, they assume shared knowledge of earlier conversations and other joint experiences. And if they are talking face to face, they assume shared knowledge of the scene around them. ‘Common ground’ is the sum of the information that people assume they share. Although the notion is often treated informally, it has a formal definition that has been essential to the study of semantics, pragmatics, and other areas of language.

History

‘Common knowledge’ as a technical notion was introduced by David Lewis (1969) to account for how people coordinate with each other. Suppose A, B, and C agree to meet at city hall at noon. The three of them take it as common knowledge that they intend to go to city hall at noon if and only if: (1) all three believe that the agreement holds; (2) the agreement indicates to all of them that they believe the agreement holds; and (3) the agreement indicates to all of them that they intend to go to city hall at noon. In Lewis’s terminology, the agreement is the ‘basis’ for A, B, and C’s common knowledge that they intend to go to city hall at noon. Common knowledge is always a property of a community of people, even though the community may consist of just two people.

The notion of ‘common ground’ was introduced, in turn, by Robert Stalnaker (1978), based on Lewis’s common knowledge, to account for the way in which information accumulates in conversation:

Roughly speaking, the presuppositions of a speaker are the propositions whose truth he takes for granted as part of the background of the conversation... Presuppositions are what is taken by the speaker to be the **common ground** of the participants in the conversation, what is treated as their **common knowledge** or **mutual knowledge** [p. 320, Stalnaker’s emphases].

In this view, people in conversation take certain propositions to be common ground, and when they make assertions, they add to this common ground. When A tells B, *George arrived home yesterday*, A takes it as common ground with B who George is, what day it is, and where George lives. A uses the

assertion to add to their common ground the proposition that George arrived home the day before. Common ground therefore also includes common (or mutual) beliefs, and common (or mutual) suppositions (Clark and Marshall, 1981; Clark, 1996).

Common ground is a reflexive, or self-referring, notion (Cohen, 1978). If A takes a proposition as common ground with B, then A takes the following statement to be true: A and B have information that the proposition is true **and that this entire statement is true**. (*This sentence has five words* is reflexive in the sense that **this sentence** refers to the sentence that contains it.) Because of the self-reference, people can, technically, draw an infinity of inferences from what they take to be common ground. Suppose A takes it that A and B mutually believe that George is home. A can infer that B believes that George is home, that B believes that A believes that George is home, that B believes that A believes that B believes that George is home, and so on *ad infinitum*. In practice, people never draw more than a few of these inferences. These iterated propositions are therefore a derivative and incomplete representation of common ground. The reflexive notion is more basic (Lewis, 1969; Clark and Marshall, 1981; Clark, 1996).

Bases for Common Ground

In conversation and other joint activities, people have to assess and reassess their common ground, and to do that, they need the right bases. These bases fall into two main categories: community membership and personal experiences (Clark, 1996).

Communal Common Ground

Common ground is information that is common to a community of people. Some of these communities are built around shared practices or expertise, such as the communities of ophthalmologists, New Zealanders, or English speakers. Once A and B mutually establish that they are both ophthalmologists, New Zealanders, or English speakers, they can take as common ground everything that is taken for granted in these communities. Even if A and B mutually establish that A is a New Zealander and B is not, they can take as common ground everything an outsider would think an insider should know about New Zealand. Common ground based on community membership is called ‘communal common ground.’

Everybody belongs to many communities at the same time. Some of these communities are nested

(e.g., North Americans, Americans, Californians, San Franciscans, Nob Hill residents), and others are cross cutting (Californians, lawyers, football fans, Christians). Both nesting and cross-cutting communities lead to gradations in common ground. Any two Californians might readily presuppose common knowledge of the Golden Gate Bridge on San Francisco Bay, but only two San Franciscans would presuppose common knowledge of Crissy Field right next to it.

People have both direct and indirect ways of establishing which communities they jointly belong to. When people meet for the first time, they often begin by exchanging information about their occupations, residences, hobbies, and other identities. They display other communal identities indirectly – in their choice of language, dialect, and vocabulary; their choice of dress and accoutrements; and their age and gender. It is remarkable how many cultural identities people can infer as they talk and how useful these are in establishing communal common ground.

Personal Common Ground

The other main basis for common ground is joint experience. The joint experience may be perceptual. When A and B look at a candle together, they can take their joint experience as a basis for certain mutual beliefs – that there is a candle between them, that it is green, that it smells of bayberry, that it is lit. Or the joint experience may be linguistic or communicative. When A tells B (on April 8), *George arrived home yesterday*, and once they mutually establish that B has understood A, the two of them can take it as common ground that George arrived home on April 7. Common ground that is based on joint perceptual or linguistic experiences between two people is called their ‘personal common ground’. It often holds only for the two of them.

Conversations and other joint activities depend on the orderly accumulation of personal common ground. Suppose A and B are assembling a television stand together. To succeed, they need to establish as common ground what each is going to do next. Part of this they accomplish linguistically, in their spoken exchanges, as when A proposes, *Let's put on this piece next*, and B takes up the proposal, *Okay*. But other parts they accomplish perceptually, as when A hands B a board, screw, or screwdriver, or when A holds up a board and they examine it together. Most face-to-face conversations depend on a mix of linguistic and perceptual bases for the accumulation of personal common ground. Telephone conversations depend almost entirely on linguistic bases.

Language and Communal Common Ground

Communal common ground is fundamental to account for the conventions of language, what are termed the ‘rules of language’. These include conventions of semantics, syntax, morphology, phonology, and pragmatics (Lewis, 1969).

Speakers ordinarily try to use words that their addressees will understand, and that requires a ‘shared lexicon.’ The problem is that every community has its own ‘communal lexicon’ (Clark, 1996). Once A and B jointly establish that they are both speakers of English, they may presuppose common knowledge of a general English-language lexicon. But because other communities are nested and cross cutting, so are the lexicons associated with them. There is a nesting of communities that speak English, North American English, New England English, and Bostonian. Although words such as *dog* and *in* are common to English in general, others are common only to one or another nested community; in Bostonian, for example, a *barnie* is a Harvard student. Indeed, every community (Californians, lawyers, football fans, ophthalmologists) has a specialized lexicon. The lexicon for lawyers includes *tort*, *mortmain*, and *ne exeat*. The lexicon for ophthalmologists includes *tonometry*, *uvea*, and *amblyopia*. To use *barnie* or *mortmain* is to take as common ground a Bostonian or legal lexicon. Communal lexicons are sometimes called jargon, dialect, patois, idiom, parlance, nomenclature, slang, argot, lingo, cant, or vernacular; or they consist of regionalisms, colloquialisms, localisms, or technical terminology.

Speakers also try to use syntactic constructions, or rules, that they share with their addressees. For example, in English generally, it is conventional to mention place before time (*George is going to London tomorrow*); yet in Dutch, a closely related language, it is conventional to mention place and time in the reverse order (*Pim gaat morgen naar London*, ‘Pim goes tomorrow to London’). The rules of syntax, however, vary by nested communities. It is conventional to say *He gave it me* in British English, but not in English generally. It is conventional to say *My car needs washed* in Western Pennsylvania English, but not in North American English. Many rules of syntax are tied to specific words in a communal lexicon, and these vary from one community to the next.

Speakers also try to use, or adapt to, the phonology of their cultural communities. Indeed, pronunciations vary enormously from one community to the next. The vowel in *can't*, for example, changes as one goes from British to North American English, from northern to southern dialects of American English, and

even from one social group to another within a single school. Also, the same person may pronounce *singing* as 'singing' in an informal setting but as 'singing' in a classroom or a court of law.

Discourse and Personal Common Ground

Personal common ground is essential to the processes by which people converse. To *communicate* is, according to its Latin roots, to *make common* – to establish something as common ground. To succeed in conversation, people must design what they say (1) against the common ground they believe they already share with their interlocutors and (2) as a way of adding to that common ground (Stalnaker, 1978). Two consequences of trying to make something common are 'information structure' and 'grounding.' 'Information structure' is a property of utterances. When A tells B, *What the committee is after is somebody at the White House*, A uses the special construction to distinguish two types of information (Prince, 1978). With the Wh-cleft *What the committee is after*, A provides information that A assumes B is already thinking about. It is one type of 'given information.' In contrast, with the remainder of the utterance 'is somebody at the White House,' A provides information that A assumes B doesn't yet know. It is 'new information.' Given information is assumed to be inferable from A and B's current common ground, whereas new information is not. New information is, instead, what is to be added to common ground. The way people refer to an object in a discourse (e.g., the committee, somebody, of the White House) depends on whether they believe that the object is readily evoked, known but unused, inferable, or brand new in their common ground for that discourse (Prince, 1981).

'Grounding' is the process of trying to establish what is said as common ground (Clark and Schaefer, 1989; Clark and Brennan, 1991). When A speaks to B in conversation, it is ordinarily not enough for A simply to produce an utterance for B. The two of them try to establish as common ground that B has understood what A meant by it well enough for current purposes. In this process, B is expected to give A periodic evidence of the state of his or her understanding, and A is expected to look for and evaluate that evidence. One way B can signal understanding is with back-channel signals such as *uh-huh*, *yeah*, a head nod, or a smile. Another way is with the appropriate next contribution, as when B answers a question asked by A. But if B does not manage to attend

to, hear, or understand A's utterance completely, the two of them will try to repair the problem. One way is illustrated here:

A (on telephone): Can I speak to Jim Johnstone, please?

B: Senior?

A: Yes.

B: Yes.

In turn 2, B asks A to clear up an ambiguous reference in A's question, and in turn 3, A does just that. Only then does B go on to answer A's question. Turns 2 and 3 are called a 'side sequence' (Jefferson, 1972). Grounding takes many other forms as well.

Common ground is central to accounts of language and language use. It is needed in accounting for the conventions, or rules, of language and to explain how people contribute to conversation and to other forms of discourse.

Context Principle

R J Stainton, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

It is a near truism of the philosophy of language that a word has meaning only in the context of a sentence; this principle is sometimes formulated as the claim that only sentences have meaning in isolation. This is the context principle, first emphasized in Western philosophy by Frege (1884), endorsed early on by Wittgenstein (1922: 51), and sanctioned more recently by Quine (1951: 42), among many others. The Principle and several different ways of understanding it seem to have been foreshadowed in classical Indian philosophy. (See also Matilal and Sen, 1988.)

In this article, I provide some background to the Principle, describe three ways of reading it (a methodological reading, a metasemantic reading, and an interpretational/psychological reading). I offer some reasons for endorsing the Principle, and some reasons for being skeptical.

The heated exegetical controversies over Frege's relationship to the Principle are not presented in this article. Some believe that Frege would have applied it to both sense and reference; others disagree. Some believe that Frege rejected the Principle in his later work, others that he retained it throughout. In addition, different authors take Frege to endorse different readings of the Principle: nearly everyone would agree that he accepted the methodological reading, but it is less clear whether he endorsed the metasemantic or interpretational/psychological reading. Such scholarly issues are not my concern in this article. For a thorough discussion, see Dummett (1981: 369ff, 1993a).

Sentence Primacy: Three Interpretations of the Context Principle

The context principle gives primacy to sentences. Specifically, sentences are taken to be semantically prior to the words that make them up. The Principle is, in this regard, a member of a family of theses that have some whole to being somehow 'prior' to its parts. As with all such doctrines, one obtains a holistic primacy thesis by specifying what the whole is, what its parts are, and in what sense the former is prior to the latter. Most important for present purposes, one can mean different things by 'prior.' Of particular interest here, one can take sentences to be methodologically prior, metasemantically prior, or interpretationally prior to the words that compose them.

Let me begin with the methodological reading of the Principle. In his *Foundations of Arithmetic*, Frege (1884: x) famously promised to keep to the following fundamental constraint: "never to ask for the meaning of a word in isolation, but only in the context of a sentence." Taken as a methodological precept, this principle essentially tells the lexical semanticist only to contemplate the effect that a word can have on sentences in which it may be embedded. For instance, to find out the meaning of the word 'one' (an example of great interest to Frege), the lexical semanticist should reflect upon such questions as the following: What whole sentences containing 'one' have in common (e.g., "One apple fell" and "One dog died"); how sentences that contain words slightly different from 'one' differ systematically in meaning from maximally similar sentences containing 'one' (e.g., "One dog died" versus "No dog died"); and so on. What the lexical semanticist should never do is try to figure out the meaning of 'one' just by thinking about it – that phrase – in isolation (where in isolation means not embedded in any larger syntactic structure).

The second reading of the context principle considered in this article is the metasemantic reading. A metasemantic view is a view about the source of meaning. It poses an "in virtue of what" question. Here's an example. Suppose we ask

- (1) In virtue of what is the sound /to:fu/ meaningful?
In virtue of what does it mean "a pale curd of varying consistency made from soybean milk," rather than "sea lion" or "watch"?

Notice that we are not asking, in (1), what the sound /to:fu/ means. Rather, we are asking why it means what it does. Nor is this the causal-historical question about the steps whereby /to:fu/ came to have this meaning. It is, instead, the issue of what more primitive present facts make for this less primitive present fact: how do the 'higher' facts emerge from 'lower' ones? For example, compare these two questions: what makes it the case that things have the monetary value they do, or what makes it the case that certain things are illegal, or rude, or immoral? These too are "in virtue of what" questions.

Some philosophers seem to have taken from Frege's discussion of "not asking for the meaning of a word in isolation" a claim about what makes words meaningful and what makes them have the meaning they do. The claim is that, fundamentally, only sentences have meaning. This is not to say that subsentences are gibberish. Rather, the entities that have meaning in the first instance are sentences. Unlike the first reading of the Principle, this doctrine is not about where one should look to find out about meaning;

it is, rather, a doctrine about where meaning comes from, i.e., the basic source of meaning. What the Principle says is that the only things that have meaning non-derivatively are sentences, so it must be in virtue of their role within sentences that subsentential expressions have meaning at all.

Here is the same idea put another way: suppose that some expressions obtain their meaning from how they alter the meanings of larger wholes. Suppose, indeed, that this is how words/phrases obtain their meaning; they therefore have meaning only derivatively, not fundamentally. Now, it cannot be the case that all expressions obtain their meaning in this way or there would be an infinite regress. The claim says that the things that have meaning non-derivatively are sentences.

Does this mean that one must first grasp the meaning of each of the infinite number of sentences in the language and only then solve for word meanings? No, not least because doing so is not humanly possible. To avoid this problem, proponents of the metasemantic version of the context principle can make several claims. First, they may insist on a sharp difference between (1) a psychological story about how humans grasp word and sentence meanings and (2) a philosophical story about the metaphysical underpinnings of word and sentence meaning. They may then eschew any claims about the first of these, stressing that they only mean to address the second (see Dummett, 1973: 4 for this approach). Second, the proponents of the context principle, read metasemantically, could propose that there is some finite cluster of simple sentences, the meaning of which one grasps from use; one then presumably solves for the meaning of the words and for the contribution of syntax, using just those sentences. Performing this finite task then gives the person the capacity to understand new sentences, a potential infinity in fact, on the basis of the (familiar) words in the (unfamiliar) sentences and how those words are structured. Either move would save the proponents of the metasemantic thesis from endorsing the absurd view that one first understands all sentences and only then understands any words.

So far we have examined two readings of the context principle. The first was merely methodological, a claim about how to find out what particular words mean: To find word meanings, look at what they contribute to sentences. The second reading was metasemantic, a claim about why words have the meanings they do: words only have meaning because of how they affect sentence meanings. The third reading of the Principle is interpretational/psychological. It is an empirical claim about the psychology underlying comprehension. Dummett (1993b: 97) discusses

the view that “it is possible to grasp the sense of a word only as it occurs in some particular sentence.”

In a way, this reading of the Principle is the most straightforward of the three: the idea underlying it is that the only things we are psychologically able to understand are whole sentences. Put in terms of generative capacity, the claim would amount to this: the only thing that our semantic competence generates are meanings for whole sentences; it does not output meanings for words/phrases (though it presumably uses word/phrase meanings in generating meanings for whole sentences, they just are never ‘output’). Thus, we can understand words only when they are spoken within whole sentences. Even this most straightforward of the three readings admits of further subreadings, however. Dummett (1993b: 109), for instance, contrasted two varieties of “grasping a sense,” one dispositional and the other occurrent. He granted that one may dispositionally grasp the sense of a subsentence outside the context of any sentence. However, he apparently denied – or anyway, has Frege deny – that one can, in the occurrent sense, grasp the sense of a word/phrase without grasping the sense of a sentence within which that word/phrase occurs. This would mean that one could “know the meaning” of a word in isolation, but that whenever one put that knowledge to work, in actual understanding, it would have to be in grasping a sentential content. This last is what the context principle would come to, on this weaker subreading of the interpretational/psychological principle.

Motivating the Context Principle

Having explained three senses in which one could take whole sentences to be prior to the words that make them up, let us consider reasons for endorsing sentence primacy. Some of these reasons support just one reading of ‘priority.’ Some support more than one. Given the limited space, I present only three such reasons and for the most part leave for the reader the question of which reason supports which reading of “Sentences are prior.”

Frege believed that, in failing to obey his methodological constraint, “one is almost forced to take as the meanings of words mental pictures or acts of the individual mind” (Frege, 1884: x). Thus in the case of number-words, the failure to respect the principle could easily lead one to suppose that ‘one’ stands for a mental item, and hence that mathematics is somehow about mental entities, which in Frege’s view is an extremely serious error (see Frege, 1884: 116). However, when one obeys the principle, one comes to the right view: the meaning of a word is not some idea that we associate with it, but is instead the thing

that the word contributes to the meaning of larger expressions. Frege writes (1884: 71):

That we can form no idea of its content is therefore no reason for denying all meaning to a word, or for excluding it from our vocabulary. We are indeed only imposed on by the opposite view because we will, when asking for the meaning of a word, consider it in isolation, which leads us to accept an idea as the meaning. Accordingly, any word for which we can find no corresponding mental picture appears to have no content. But we ought always to keep before our eyes a complete proposition. Only in a proposition [Satz] have the words really a meaning.

So, one advantage of endorsing the Principle is that it keeps us from making such a mistake.

Consider this related motivation: starting from the top – focusing on whole sentence meanings and only then considering what the parts must mean, in order for the observed whole meaning to be generated – opens up the possibility of novel and surprising accounts of what the parts mean. Indeed, it becomes possible to conceive of syntactic parts that, though they have some sort of impact on meaning, do not themselves have a meaning in isolation. Such parts receive only what is called a ‘contextual definition.’ This concept is best explained by appeal to an example. If we start by looking at the phrasal parts of “The king of France is bald,” asking what they mean, it can seem inevitable that the phrase, “The king of France,” must stand for an object. What else could its meaning be, in isolation? This, of course, raises all manner of ontological issues: What is this bizarre object, since there is, in reality, no king of France? How can such an unreal entity be bald or not, so as to render this sentence true or false? And so on. Crucially, however, if we pursue the methodology suggested here and start with the whole sentence, we may notice, with Russell (1905), that the sentence as a whole means the following: there is exactly one king of France, and every king of France is bald. We may further notice that this whole meaning can be generated without assigning any reference at all to the phrase, “The king of France.” This is not to say that this phrase makes no difference to what the whole means; patently it does make a difference. However, in place of a meaning-entity for “The king of France,” all we need is a rule, a contextual definition, that says:

- (2) A sentence of the form “The *F* is *G*” is true iff exactly one thing is *F* and everything that is *F* is *G*.

Taking this contextual definition to be the meaning-determining rule, we simply avoid the issue of what the phrase, “The king of France,” stands for, since the phrase itself, upon analysis, does not contribute a constituent to the whole meaning.

Another methodological advantage of the context principle, then, is that it is rather easier to arrive at this kind of contextual definition than if we begin with what the parts mean, in isolation.

A second kind of advantage is that, by strictly obeying the context principle, we automatically meet a key constraint of semantic theories: compositionality. Roughly speaking, compositionality says that the meaning of a whole expression is exhausted by (1) what its parts mean, and (2) how those parts are put together (*see Compositionality: Semantic Aspects, Compositionality: Philosophical Aspects* for more details.) Compositionality is accepted as a constraint for two related reasons. First, insofar as these are the sole determinants of whole meanings, we can explain why people understand complex expressions that they have never encountered before: they understand them by calculating the whole meaning from precisely these two elements, both of which are familiar. Second, were whole meanings not compositional, it would be an utter mystery how we finite beings could in principle know the meaning of the infinite number of sentences that, though we have never heard them, we would, but for our finite lifetime and memory, be capable of understanding. That is, compositionality accounts for an observed ability in practice and a different though related ability in principle. Notice, however, that compositionality is one side of a coin, the other side of which is the context principle. Compositionality says that whole meaning is entirely a function of part meanings plus structure:

- (3) Whole meaning = $\langle \text{part-meaning}_1, \text{part-meaning}_2, \dots, \text{part-meaning}_i, \dots, \text{part-meaning}_n \rangle + \text{structure}$

The context principle employs this same equation to solve for a part meaning, i.e., taking part meaning to be entirely determined by the whole meaning, the meanings of the other parts, and the structure:

- (4) $\text{Part-meaning}_i = \text{Whole meaning} - \langle \text{part-meaning}_1, \text{part-meaning}_2, \dots, \text{part-meaning}_n \rangle + \text{structure}$

So, if we assign part meanings in line with (4), the context principle, we cannot help but get the desired result vis-à-vis (3), i.e., compositionality. (Note: obviously the manner of combination of part meanings and structure is not literally addition. Nevertheless, I use the symbols ‘+’ and ‘−’ to simplify presentation.) Automatically satisfying the compositionality constraint in this way is thus another advantage of endorsing the context principle.

A third kind of motivation for endorsing the Principle is that it seems to be connected with several

other holistic primacy theses, each of which is allegedly independently motivated. (Unfortunately, space does not permit me to explain what the independent motivation is for these other theses. See Brandom, 1994, chapter 2, sections II and III, for discussion and an overview of the relations among these various primacy claims.) Kant (1787) famously insisted that judgment is prior to perception of individuals: seeing that María is a female, a person, tall, and the like is prior to seeing María. Put otherwise, whereas classical empiricists started with representations of individual objects and of universals and then built up complex mental representations that could be true/false, Kant turned this on its head: the whole representation (i.e., what is judged) is prior to the object-denoting parts that make it up. The early Wittgenstein (1922: 31) also insisted that facts are prior to the objects and properties that make them up: “the world is the totality of facts, not of things.” In a related move, Dummett (1973) has urged, following the later Wittgenstein, that the practice of assertion – and other full-fledged “moves in the language game” – is prior to the act of referring. As Wittgenstein (1953: 24) put it:

For naming and describing do not stand on the same level: naming is a preparation for description. Naming is so far not a move in the language-game – any more than putting a piece in its place on the board is a move in chess. We may say: *nothing* has so far been done, when a thing has been named. It has not even *got* a name except in the language-game. This was what Frege meant too, when he said that a word had meaning only as part of a sentence.

Adopting these primacy theses can, each in their own way, lead one to expect sentences to be primary as well. Goes the idea, what is judged are sentential representations; the linguistic item that corresponds to a fact is a sentence, and the linguistic item that we assert with is the sentence.

Dummett’s point about sentence use deserves to be expanded upon, since it underlies several of the points made above. Dummett suggested that the only things that can be used in isolation – that is, used without being embedded in a larger structure – are sentences. He wrote (1973: 194):

A sentence is, as we have said, the smallest unit of language with which a linguistic act can be accomplished, with which a “move can be made in the language-game”: so you cannot *do* anything with a word – cannot effect any conventional (linguistic) act by uttering it – save by uttering some sentence containing that word.

Yet, as a famous Wittgensteinian slogan says, meaning comes from use (see Wittgenstein, 1953 and elsewhere). Thus, the things that have meaning

fundamentally have it because of their use: an expression has the non-derivative meaning that it does because of the kinds of actions speakers can perform with it. However, as suggested just above, those just are the sentences. So words must get their meaning because they appear in meaningful sentences. Dummett, expanding on this Wittgensteinian theme, put the general lesson as follows:

Indeed, it is certainly part of the content of the dictum [i.e., the context principle] that sentences play a special role in language: that, since it is by means of them alone that anything can be *said*, that is, any linguistic act (of assertion, question, command, etc.) can be performed, the sense of any expression less than a complete sentence must consist only in the contribution it makes to determining the content of a sentence in which it may occur (1973: 495; see also Dummett, 1993a).

A Possible Objection to the Context Principle

Having noted three kinds of reasons for embracing the context principle, let me end with an objection that may come immediately to mind. First, it seems that adults speak in subsentences all the time. I see a woman wearing a lovely garment and say to my wife, “Nice dress.” I receive a letter in the mail, hold it up, and say to my companion, “From Spain.” Such talk is absolutely ubiquitous. (For empirical support, see the papers in Elugardo and Stainton, 2004, and the many references cited there; for an overview, see Stainton, 2004.) Second, children learning a language seem to start with subsentences – which makes it equally hard to see how grasping a sentential meaning could be a prerequisite for grasping a subsentential one. Let us consider the problem that such subsentential speech might pose for the Principle.

Start with the methodological reading. It is a bit strong to demand that one never consider the word in isolation if words/phrases can be used unembedded to perform speech acts. More appropriate, and still in the broadly Fregean spirit, would be this claim: never *only* consider the word in isolation, but instead *also* consider its behavior when embedded in whole sentences. Non-sentential speech does not conflict with this latter, more inclusive, methodological precept. In addition, the methodological point of the context principle – to cure one of the habit of taking mental images and such as meanings – is met even on this weaker reading. Hence subsentence use actually poses no problems for the Principle, on this first reading.

What of the metasemantic doctrine? Notice that a key premise in the argument for the doctrine was

that only sentences can be used to perform speech acts. Words and phrases cannot be: that is why they were denied meaning, fundamentally speaking. Yet, this key premise looks false, if words really can be used in isolation. Therefore, without this premise, some other argument must be given for the conclusion that only sentences have meaning fundamentally. Thus subsentence use, if genuine, does not falsify the Principle read in this way, but it does leave one in need of an empirically adequate argument for meaning having to come from sentences alone.

It might seem that a better argument for the claim that meaning must still come from sentences is at hand: Surely this doctrine is required to preserve compositionality. As I stressed above, you do not get (3) above unless you also accept (4) and (4) requires that word meanings – the meaning of the parts – not exceed what they contribute to full sentences. In fact, however, compositionality does not, on its own, support the metasemantic doctrine, which makes two claims: first, sentences are a metaphysical *source* of word meaning, and second, they are the *only* such source. Neither of these claims, however, can be inferred from compositionality *per se*. All (4) gives us is a constraint: Whatever story we tell about where a word's meaning comes from, it must be consistent with sentence meanings being exhausted by what their parts mean. This does not support any claim about sources. Moreover, if words are used in isolation, then, though sentence use might be one source, it surely would not be the only one.

To see why compositionality does not, taken alone, support the metasemantic doctrine, consider an analogy. Take this proposal: facts about what art works are beautiful derive from facts about what works are attractive to (most) art experts. That is, it is in virtue of the judgment of (most) experts that art works are beautiful or not. Suppose one tried to defend this meta-esthetic view by saying: "Look, it can't be that most genuine experts are wrong about what's beautiful. They wouldn't be experts otherwise." This defense would not really succeed as an argument for the meta-esthetic view because, even granting it, one could only infer that it is a constraint on where beauty comes from that most experts are right about what is beautiful. This fact would not, on its own, support the idea that beauty comes from expert judgment. Nor would it support the even stronger idea that beauty comes solely from expert judgment. In the same way, compositionality may well impose a constraint on metasemantic theories: one might well contend that any successful metasemantics must have whole meanings exhaustively determined by part meanings and linguistic structure. Yet, one cannot go from such a constraint

immediately to conclusions about where meaning-facts emerge from; still less can one move from such a constraint to a conclusion about the sole thing from which they emerge. In sum, given subsentential speech, we are still in need of a reason for embracing the metasemantic reading of the context principle.

Let me now make a brief detour into a related issue. One reason that it matters whether the metasemantic doctrine is upheld is this: If sentence meaning is the only source of word meaning, then it is arguable that the latter is indeterminate. That is, there might be no fact of the matter about what individual words "really mean." The argument goes like this. We can hold constant the meaning of every sentence in the language while varying the contribution that we assign to the words within those sentences. To give a highly simplified example, one way to assign the right meaning to the Spanish sentence, "María no fuma" ["María doesn't smoke"] is to assign the person MARIA to 'María', SMOKEs to 'fuma', and DOESN'T to 'no'. Another way, which still gives the right meaning for the whole sentence, is to assign the person MARIA to 'María no' and DOESN'T SMOKE to 'fuma'. Now, with respect to this highly simplified example, we can find reasons for picking the first over the second option: 'fuma', 'no' and 'María' show up in lots of sentences, and their contribution in those other sentences is, surely, SMOKEs, DOESN'T, and MARIA, respectively. So that is what they contribute here too. However, suppose we revised our view of the meaning of the other parts in all sentences containing 'fuma', 'María' and 'no'. Surprisingly, it has been suggested that this sort of rearrangement is something we could systematically do. The result would be that the complete set of sentences containing a given word leaves us with various options about what the word means. Further, assuming that the meaning of all sentences in which a word occurs is the sole thing that metaphysically determines its meaning, there can be no single thing that is "the meaning of 'fuma'." This is the thesis of indeterminacy (see Quine, 1960 and Putnam, 1981 for worked-out examples).

I introduce the indeterminacy thesis because it highlights the sense in which the metasemantic version of the context principle says more than "the meanings one assigns to words must fit with the meanings one assigns to sentences containing those words." It also says that the word meanings are *exhausted* by sentence meanings – in a way that can lead to indeterminacy. In contrast, if word meanings depend also upon how words are used on their own, then even if the complete set of sentence meanings does not fix the meaning of individual words, we cannot yet conclude that word meaning

is indeterminate. For word meaning might be more completely fixed by how words in isolation are used (for more on this connection between the context principle and indeterminacy, see Stainton, 2000).

We have seen that subsentence use is consistent with the methodological reading of the context principle. It is also consistent with the metasemantic reading, though it leaves this latter doctrine in need of an empirically adequate supporting argument. Consider finally the interpretational/psychological doctrine. It says that, as a matter of our psychology, we cannot understand a word, when uttered, unless it is embedded in a sentence. This reading of the context principle seems simply false, given the existence of subsentential speech. There is no hope for making it consistent with genuine subsentence use. Apparently, hearers understand subsentential expressions in isolation; hence their semantic competence must generate a meaning for such expressions in isolation. The best hope for the Principle read in this strongest way is thus to deny that the phenomenon of subsentential speech is genuine: adults do not actually speak in subsentences, they merely appear to do so. What is really going on is that adults speak ‘elliptically’ in some sense – they produce sentences, but those sentences somehow “sound abbreviated” (see Stanley, 2000 for this sort of idea). As for children, who seem to grasp word meanings long before they grasp the meanings of any sentences, proponents of the interpretational reading of the context principle must make some fairly implausible suggestions. They may insist that children actually do understand sentence meanings even though they do not speak in sentences; or they may claim that what children mean by their words (e.g., ‘doggie’) is not what the adult word means. The child’s expression, they might insist, is actually a one-word sentence meaning, “There is a dog,” and hence is not synonymous with our word. (That is, on this second disjunct, the idea would be that children actually do not employ/understand *our* words outside sentences, but rather they employ homophonous sentences – until, that is, they are also competent with *our* sentences.)

Does this inconsistency with the interpretational/psychological reading mean that the other primacy doctrines – of judgment, facts, and assertion – are also required to make these implausible empirical claims? After all, it was suggested that those doctrines supported sentence primacy. The answer is no, because these other primacy doctrines really do not entail anything about only sentences being used and only sentence meanings being graspable occurrently. At best what they lend credence to is the primacy of a certain sort of content, namely the proposition. For, strictly speaking, it is propositions that are judged,

propositions that correspond to facts, and propositions that are exchanged in assertion. Further, subsentential speech does not call the centrality of propositions into question: When I say “Nice dress” or “From Spain,” I still convey something propositional; that is, a proposition about the salient dress to the effect that it is nice, and a proposition about the letter to the effect that it is from Spain, respectively. I merely do so using *linguistic expressions* that are not propositional. So, subsentential speech leaves proposition primacy intact. To move immediately and without further argument to any conclusion about the syntactic structures that (purportedly) express propositions, however, is to commit some kind of global use/mention error, running together features of a content (i.e., a proposition) with features of its supposed linguistic ‘vehicle’ (i.e., a sentence). In short, even if one takes judgments, facts, or assertions to be primary, one need not endorse the context principle vis-à-vis interpretation – since the latter is about the centrality of a certain class of syntactic items.

In summary, I have presented three different ways of reading the context principle: methodological, metasemantic, and interpretational/psychological. I then noted three rationales for embracing the Principle: to avoid the errors of psychologism, to enforce compositionality, and because of links to other independently motivated ‘primacy doctrines.’ I ended with an objection to the Principle, from non-sentence use. The suggested result, in the face of this objection, was two parts consistency and one part inconsistency: (1) the first reading of the Principle would be untouched, (2) the second would be left unsupported, but (3) the third reading would be outright falsified, so that the proponent of this reading of the Principle must make some (implausible) empirical claims to the effect that people do not actually speak subsententially.

Contextualism in Epistemology

H Jackman, York University, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

For a subject to truly be said to 'know' a proposition p , p has to be true, and the subject has to have a belief that p meets certain standards of justification. The invariantist will argue that, for any given proposition, the *same* standards are always in place. (The skeptical invariantist will usually take these to be very high standards, while the dogmatist will usually take them to be comparatively low.) By contrast, contextualists argue that the standards for the truth of knowledge attributions can vary from context to context. Consequently, in some contexts being able to answer skeptical doubts about our being, say, brains in vats tricked into thinking that we are experiencing a physical environment rather than a machine simulation, may be required to count as knowing that we have hands, while no such requirement may be in place in other contexts.

According to the contextualist, just as context shifts the satisfaction conditions of words like 'he' or 'tall,' context can shift the satisfaction conditions for 'know.' Contextualism has considerable appeal, since it seems clear that the standards associated with our use of 'know' show *some* sort of contextual variation. In everyday contexts, we claim to know all sorts of things; if the stakes are higher, we may claim to know less, and when faced with skeptical arguments, we may admit to knowing almost nothing. Contextualists can take the truth conditions of knowledge claims to vary the way our practice suggests. It thus both explains the intuitive pull of skepticism (skeptical arguments raise the standards for

knowledge attribution) and allows that the soundness of skeptical arguments doesn't undermine the truth of everyday knowledge claims.

Nevertheless, invariantists have argued that the contextual variation in our use of 'know' should not be reflected in the term's semantics. Instead, they suggest that some aspect of our practice (either the everyday knowledge claims or our capitulation to skeptical arguments) is either (1) systematically in error, or (2) motivated more by pragmatic rather than semantic considerations. Both strategies have the advantage of positing a simpler, context-invariant, semantics for 'know,' but the required supplementary explanations of why our use of the term varies from the proposed semantics have often seemed suspiciously *ad hoc*.

However, even if we were to admit that the semantics of 'know' is context sensitive in some way, there is still a question of which context it is sensitive to. Three possible candidates for this context are the following:

1. The subject's context: The context in which the purported knower is in.
2. The attributor's context: The context in which the claim is made that the subject does, or does not, know a given proposition.
3. The assessor's context: The context in which the claim about the subject's (lack of) knowledge is evaluated as either true or false.

When one considers one's own first-person present-tense knowledge claims such as "I know that it's raining," all three contexts can overlap. However, if A claims, "It's raining," and B later claims, "A knew that it was raining," the subject's and attributor's

context will be different. Furthermore, if C goes on to claim that “B’s claim that A knew that it was raining was false,” the context of assessment will be different from the former two as well.

How radical a doctrine contextualism will turn out to be will depend largely on which context knowledge claims are taken to be relative to.

The least radical of these takes the subject’s context to be the relevant one. For instance, if A sees his cell phone across the table, and nothing much hangs on the issue, then he may count as knowing that his phone is nearby. On the other hand, if A is expecting a particularly urgent call on his phone, he might not count as knowing without picking the phone up to make sure that it is his rather than just another phone of the same type. Still, there will be nothing subjective about whether or not a person counts as knowing a given proposition. If the subject is in the low-standards context, then anyone who denies that the subject knows that his phone is in the room will be mistaken, no matter what context the particular attributor is in.

However, subject-based contextualism does not seem to capture the way in which the standards associated with our use of ‘know’ seem to vary. For instance, if the subject’s context changes such that he will no longer be able to claim that he knows that his phone is across the room (say, he receives an e-mail telling him to expect the urgent call), he will not say that, five minutes prior to this change he did know, but now he no longer does. Rather, he will now say that he didn’t know before either, which suggests that the standards vary not according to the context that the subject is in, but rather with something else (DeRose, 2002; Hawthorn, 2004).

Of course, it will be possible to explain the differences between these aspects of our use of ‘know’ and the first sort of contextualism by appealing to linguistic error or pragmatic factors to explain the divergence, but to the extent to which one claims that we are simply mistaken about the truth conditions of our knowledge claims, the contextualist’s methodological advantage over the invariantist will seem to disappear.

On the other hand, cases like that just mentioned can be handled if we take the context of attribution to be the relevant one. On such attributer-based contextualism, it will be possible for two attributors to make seemingly conflicting true claims about whether A knows that his cell phone is in the room. If attributor B is in a low-standards context, he may truly claim that A knows that his phone is in the room, while if attributor C is in a context with higher standards, he may truly claim that A does not know this. The standards that are relevant for knowledge

are determined not (exclusively) by A’s situation, but also by B’s and C’s contexts, and considerations that are relevant for B and C might not be so for A. Knowledge attributions will thus be in an important sense, relative, since B and C can make seemingly conflicting true claims about A. The relativism involved here is, however, comparatively harmless, since there is a good sense in which B’s and C’s claims do not really conflict. Again, ‘know,’ on such an account, would be context sensitive in the way that, say, ‘tall’ is. If my 10-year-old cousin is 5’6”, he may be described as “tall” when we are discussing the prospects of his third-grade basketball team, or he may be described as “not tall at all” when we are discussing which members of my family could still sit comfortably in the back seat of a compact car. The second claim needn’t contradict the first, and many would say that both claims can be true, it’s just that the standard for being ‘tall’ is different in the two contexts.

While such attributer-based contextualism is probably the most popular version of the view (DeRose, 1992, 1995, 2002; Lewis, 1996; Neta, 2002, 2003; Williams, 1991), it fails to track some fairly well-entrenched aspects of our use of ‘know.’ In particular, when the standards for knowledge attributions go up, not only do we (1) refuse to claim that we know things that we claimed to know before, and (2) no longer claim that we knew those things in the past, but we also (3) claim that our earlier claims to know them were false (Hawthorn, 2004; MacFarlane, 2005). We will take back earlier knowledge claims, even if we recognize that the context of attribution has changed. In this respect, ‘know’ seems quite different from words like ‘tall,’ which are more plausibly tied to their contexts of attribution. When I move from a third-grade to an adult context, I will no longer refer to my 10-year-old cousin as ‘tall,’ but I will not take back my earlier characterization of him as tall or admit that it was mistaken. I’d be more likely to flag the original context of attribution, saying something like, “I meant tall for a 10 year old,” than concede that my original claim was false. By contrast, when the skeptic challenges my knowledge claim, I’m not inclined to simply respond with something like, “I meant ‘know’ in the ‘easy’ sense.” Rather, if I find the skeptic’s arguments convincing, I’ll come to view my older knowledge claims as false.

Cases like this last one can be handled by adopting the more radical stance of claiming that the assessor’s context determines which standards are relevant for knowledge attributions (MacFarlane, 2005). Such assessor-based contextualism will lead to a much more robust relativism about knowledge. On such a view, relative to C’s context, not only will A not know

that his cell phone is in the room but B's claim that A does know this will also be false. In much the same way, relative to B's context, A knows that his cell phone is in the room, and C's claim that he doesn't know this is false. On this view, then, not only can a particular sentence ("John is tall" or "Peter knows that it is raining") be true when asserted in one context and false when asserted in another but also the same assertion of a sentence can be true relative to one context of assessment and false relative to another.

This last form of contextualism may do the best job of tracking our own use of epistemic terms, but the degree to which it requires us to complicate not only our general semantic framework but also our conception of truth may seem too radical for some. For these, it may seem more promising to simplify the semantics by trying to explain away those aspects of our practice that support the assessor-based view. Once again, however, more moderate contextualists will risk sliding to invariantism if these same strategies for explaining away part of our practice can be extended to the rest of those aspects of our use that conflict with invariantism.

Conventions in Language

M Kölbel, University of Birmingham, Birmingham, UK

Independently of the question of what exactly linguistic meaning is (see **Meaning: Overview of Philosophical Theories**), a question arises as to the nature of its attachment to linguistic expressions: why does the word 'banana' mean what it does rather than something else? Why doesn't some other word have the meaning that 'banana' actually has? The answer almost everyone agrees upon is that it is a matter of convention that words mean what they do. Had there been different conventions of language, then words

would have had different meaning. Views diverge, however, on the significance of the conventionality of language, on the question of what exactly a convention of language is, and on the extent to which meaning is conventional (as opposed to, say, inferential). In what follows the focus will be mainly on the second of these issues, i.e., on the nature of linguistic conventions.

Convention and Analyticity

In the background of current thinking on language conventions is the attempt of the logical empiricists to

explain *a priori* knowledge as knowledge of analytic truths, i.e., propositions that are true in virtue of meaning (Carnap, 1947; Ayer, 1946; *see Analytic/Synthetic, Necessary/Contingent, and a Priori/a Posteriori: Distinction and A Priori Knowledge: Linguistic Aspects*). An example are the truths of arithmetic: while Kant had thought they were synthetic (not true in virtue of meaning), Ayer and Carnap followed Frege in claiming that they are analytic, i.e., true by definition. Carnap extended this approach to modality: necessary truths are just those that are true in virtue of linguistic rules.

Conventionalism was opposed by Quine, who argued against Carnap that there is no coherent way of drawing a distinction between analytic and synthetic truths (Quine, 1951, 1960). According to Quine, it is impossible to separate the conventional from the empirical ingredient of any truth, because every attempt to explicate analyticity will ultimately rely on some other inexplicable semantic notion, such as synonymy or possibility.

The debate between Carnap and Quine forms the historical background for recent efforts to explain in detail how language is conventional. The most influential account is that by David Lewis (1969, 1983), who provided a game-theoretic account of convention in general and then explained the specific nature of conventions of language within this framework. However, Lewis's account built on Grice's earlier analysis of linguistic meaning in terms of speaker intentions.

Grice

Grice claimed that linguistic meaning is ultimately a matter of the communicative intentions of speakers (Grice, 1989). Grice started by defining a notion of speaker meaning ('non-natural meaning') in terms of speaker intentions and then analyzed the meaning of expression types in terms of their use by speakers to speaker-mean something with them (*see Expression Meaning versus Utterance/Speaker Meaning*). He defined speaker-meaning as follows: a speaker *S* speaker-means that *p* by uttering *s* just if in uttering *s* *S* intends his or her audience to think that (*S* believes that) *p* on the basis of the audience's recognition of that very intention (Grice, 1989: 213–223, 123). For Grice, the meaning of expression types depended on what speakers in a speech community use these types to speaker-mean on particular occasions of use. A little more precisely, the dependence is as follows: a sentence type *s* means that *p* in a community *C* just if members of *C* have the habit of speaker-meaning that *p* by uttering *s*, and they retain the habit conditionally upon other members doing likewise. In short,

words mean what they do because speakers use these words habitually with certain communicative intentions, and this habitual procedure is conditional upon other speakers doing likewise. (For the fine details of the account, see Grice, 1989: 124–128.)

Lewis

Grice's analysis of linguistic meaning in terms of speaker intentions was initially perceived to be in competition with accounts offered by formal semanticists (see e.g., Strawson, 1969). The formal semanticist's central notion in the explanation of meaning is not that of intention but that of a 'truth condition.' However, it now seems that the two approaches can complement each other, and need not be viewed as competitors. Formal semanticists study artificial languages (which often serve as models of fragments of natural languages) with the aim of elucidating phenomena of compositionality (*see Compositionality: Philosophical Aspects and Formal Semantics*). Grice's framework does not address questions of compositionality, but it can in fact accommodate the formal semanticists' approach. David Lewis's theory of linguistic conventions not only showed how the insights of formal semantics can be appropriated within Grice's theory of communicative intentions; it also offered a detailed explication of the notion of convention itself (Lewis, 1969, 1983).

According to Lewis, there is a vast range of possible languages. Restricting himself initially to simple cases (languages with only context-insensitive declarative sentences), Lewis thought of a possible language as a function from a domain of sentences into a range of truth conditions. Many of the languages described by formal semanticists are possible languages in this sense. Most possible languages, however, are not used by anyone. According to Lewis, this is where convention plays a key role. He used his game-theoretic notion of convention to specify under what conditions a possible language is an actual language, i.e., is actually used by a population of language users.

Lewis's General Notion of Convention

Any word could in principle be used to mean anything. If two language users are to communicate successfully they therefore need to coordinate their use of words and make sure they use the same words with the same meaning. This type of situation, where several agents have a common interest in coordinating their actions, is called a 'coordination problem.' Conventions are a way of solving coordination problems – linguistic conventions are just a special case of this more general phenomenon.

According to Lewis, conventions (linguistic or not) are regularities in the behavior of the agents of a population. These regularities arise from the common interest of the agents to coordinate their actions and is sustained because each agent expects the others to conform to the regularity and prefers to conform him- or herself if the others conform. There are potential alternative regularities which could also secure coordination, hence the need for a convention.

For example, if our phone conversation is interrupted and we have the common aim of continuing the conversation, then there are two alternatives: either I phone back and you wait, or you phone back and I wait. No other combination of actions will achieve our common aim. Each of us prefers to phone back if the other waits and prefers to wait if the other phones back. But how do we know what the other is doing? If the problem is a recurrent one, then a convention can help. For example, if each of us expects the other to phone back just if the other was the original caller and not to phone back otherwise, then each of us will prefer to phone back if and only if he or she was the original caller.

Lewis's definition of convention is roughly as follows (see Lewis, 1983: 165 for full details): a regularity *R* is a convention in a population *P*, just if

1. everyone conforms to *R*;
2. everyone believes that the others conform to *R*;
3. the belief that the others conform to *R* gives everyone a decisive reason to conform to *R* him- or herself;
4. *R* is not the only regularity meeting (3);
5. (1)–(4) are common knowledge among *P*: they are known to everyone, it is known to everyone that they are known to everyone, etc.

Conventions of Language

Lewis used the above definition of convention in his explication of what it is for any of the many possible languages (as described by a semantic theory) to be the language actually used by a population. According to Lewis, a population *P* uses a possible language *L* just if members of *P* have a convention of uttering sentences of *L* only if they are true in *L*, and of coming to believe in the truth in *L* of sentences that are uttered by others. The relevant coordination problem for a population here is the problem of converging on one possible language. It is in the interest of each member to use the language the other members are using because there is a common interest in communication. Lewis called this a “convention of truthfulness and trust.”

There are some difficulties of detail that can be resolved by further refinements. For example, the proposal as sketched above does not take into account indexical languages or languages with non-declarative sentences (e.g., interrogative sentences). Lewis himself discussed how his approach can be suitably extended (Lewis, 1983). Another difficulty is the fact that too few speakers try to utter only sentences that are true in their language, and similarly too few speakers believe everything they are told. There is therefore no convention of truthfulness and trust in English among English speakers. Lewis's account can be modified to deal with this problem. For example, instead of saying that users of a language try to utter only sentences that are true in that language, Lewis could say that they utter sentences only if they **accept**, or want to commit themselves to, their truth for the purposes of the conversation.

A Basic Difficulty for Grice–Lewis

There are also some more fundamental difficulties, which concern the basic assumptions on which the Grice–Lewis approach is built. It is part of both Grice's and Lewis's accounts to attribute to language users highly complex mental states. On both accounts, language users are required to have unrealistically complex iterated preferences and beliefs concerning other language users (see definitions above). Typical language users, however, do not report these mental states. Lewis's response to these doubts concerning the psychological reality of these mental processes was to say that they are merely ‘potential’: users would explicitly have these cognitive states if they bothered to think hard enough (Lewis, 1983: 165) and presumably they would also be able to report these intentions if they thought hard enough. However, it is unclear whether the phrase ‘hard enough’ is substantial enough to render the theory empirically testable. Would Lewis accuse anyone denying the psychological reality of the account of not thinking hard enough?

Some psychological findings seem to add weight to this line of objection. The fundamental assumption behind Grice's and Lewis's approaches is that linguistic behavior is a product of a special case of instrumental reasoning. This much seems to be implied by Grice's idea that linguistic meaning is a matter of communicative intentions and linguistic behavior a special case of intentional action. As Laurence (1996) pointed out, however, there are cases which suggest that language processing and instrumental reasoning are independent faculties. A disability in instrumental reasoning

can be accompanied by full linguistic abilities. Conversely, lack of linguistic abilities can be accompanied by fully functioning instrumental reasoning.

Chomskyan Accounts of Linguistic Convention

A Chomskyan view of language processing lends itself to a different account of linguistic convention. Any account of linguistic convention needs to preserve the idea that what a given word means is a contingent and largely arbitrary matter; that words could have meant something other than what they actually mean, and that other words could have meant what they actually do. Laurence (1996) argued that a Chomskyan view does preserve this idea.

On such a Chomskyan view, language processing is performed by a special language-processing faculty. This faculty processes language at various levels, phonologically, syntactically, and semantically. At each level, the faculty associates certain representations with utterances. On this view, one might say that the various representations the language faculties of a group associate with a given utterance determine that utterance's meaning in the language of that group. The meaning of an expression type would then be a function of the representations the language faculties would associate with any utterances of that type.

On this view of the meaning of expression types, it does indeed turn out to be contingent: each type might have meant something other than it actually means, etc. For the precise working of the language faculty in an adult is partly the result of environmental influences. Within the constraints of universal grammar, children learn the language spoken in their surroundings. Thus, the representations computed by a given language faculty will depend in part on the language-learning environment. Had the environment been different, the representations associated by the language processor would have been different, thus its meaning would have been different.

This model works best for the conventions of a language spoken by people who have learnt the language in the natural way. But it would also explain explicit linguistic conventions (e.g., when a new technical term is explicitly introduced in a scientific paper, or when an adult learns a natural language). Presumably, these are cases where instrumental reasoning provides input for, and interacts with, the separate language-processing faculty.

Convention versus Inference

The controversy between Griceans and Chomskyans concerns the role of instrumental reasoning in the

determination of what expressions conventionally mean. There is another controversy, again involving Grice at centre stage, concerning the extent to which the meaning of utterances is the product of the conventional meaning of the expression types used as opposed to other, linguistically unanticipated, inferences. Grice distinguished between what is literally said by an utterance from what is 'implicated' (see **Semantics–Pragmatics Boundary**). What is literally said is more or less determined by the conventional meaning of the expressions used. However, language users often aim to convey messages that go beyond what is literally said, such as the polite referee in Grice's famous example: when the referee says "the candidate has an excellent command of English" he is relying on the audience's ability to infer that he wished to convey that the candidate is no good at philosophy (see Grice, 1989: 33).

The controversy concerns which aspects of communication should be viewed as arising from pragmatic inferences, as in the case of Gricean implicatures, and which aspects should be viewed as pertaining to literal meaning. (Another related question is whether any implicature can be conventional.) Davidson is at one end of the spectrum of possible views here: he practically denies (in good Quinean fashion) that there is any conventional meaning. It may be helpful in interpreting an utterance to start with a conjecture that the expression types uttered have certain stable meaning, but ultimately such a conjecture is merely a 'crutch' (Davidson, 1984: 279). (For more on these questions see Recanati, 2004; also **Semantics–Pragmatics Boundary** and **Nonstandard Language Use**).

Cooperative Principle

K Lindblom, Stony Brook University, Stony Brook, NY, USA

The Principle Itself

In his William James Lectures at Harvard University in 1967, H. Paul Grice posited a general set of rules contributors to ordinary conversation were generally expected to follow. He named it the Cooperative Principle (CP), and formulated it as follows:

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged (Grice, 1989: 26).

At first glance, the Cooperative Principle may appear an idealistic representation of actual human communication. After all, as Grice himself has learned from his detractors, many believe "...even in the talk-exchanges of civilized people browbeating disputation and conversational sharp practices are far too common to be offenses against the fundamental dictates of conversational practice." Further, even if one discounts the tone of an exchange, "much of our talk exchange is too haphazard to be directed toward an end cooperative or otherwise" (Grice, 1989: 369).

However, Grice never intended his use of the word 'cooperation' to indicate an ideal view of communication. Rather, Grice was trying to describe how it happens that – despite the haphazard or even agonistic nature of much ordinary human communication – most discourse participants are quite capable of making themselves understood and capable of understanding most others in the course of their daily business.

What Counts as Cooperation?

Grice invites us to consider the following, quite unextraordinary exchange:

A: I am out of petrol.

B: There is a garage round the corner (Grice, 1989: 32).

Assuming A immediately proceeds to the garage, secures the petrol, and refills his car, we may describe B's contribution as having been successful. By what rational process of thought was A so quickly able to come to the conclusion that the garage to which B refers would fulfill his need for petrol? Why did B's utterance work? Grice's answer: because A and B adhere to the Cooperative Principle of Discourse.

It is not hard to imagine that two friends sharing a ride would want to help each other through a minor crisis; thus, 'cooperation' in this scenario seems quite apt.

But imagine the exchange went this way instead:

A: I am out of petrol.

B: (sarcastically) How nice that you pay such close attention to important details.

In this second scenario, not only does B refuse to assist A in solving the problem, he uses the occasion to add to A's conundrum an assault upon his character. Assuming A feels the sting, again B's contribution has been successful. So how and why in this case has B's contribution worked? How can such a sour response as B's callous retort be considered 'cooperative'? Again, Grice's Cooperative Principle proves a useful answer. The explanation requires closer inspection of the strictness with which Grice uses the term.

The Cooperative Principle and the Maxims of Cooperative Discourse

Grice explicates his Cooperative Principle of Discourse in 'Logic and Conversation,' the paper originally presented at Harvard University in 1967, later printed in Cole and Morgan (1975), and reprinted in a slightly revised version in Grice's *Studies in the Way of Words* (1989). We cite from his final version as we assume this is the one he considered most complete. In the essay, Grice is careful to limit use of the CP for describing only talk exchanges that exhibit the following three specific characteristics:

1. The participants have some common immediate aim.
2. The contributions of the participants [are] dovetailed, mutually dependent.

3. There is some sort of understanding (often tacit) that, other things being equal, the transactions should continue in appropriate style unless both parties are agreeable that it should terminate (Grice, 1989: 29).

Though he is careful to limit the CP's application to talk exchanges that exhibit these particular cooperative characteristics, this list should not be read as an admission of great limitation. For Grice finds that most talk exchanges **do** follow the CP because most talk exchanges do, in fact, exhibit the **cooperative** characteristics he outlines:

Our talk exchanges ... are characteristically, to some degree at least, cooperative efforts; and each participant recognizes in them, to some extent, a common purpose or set of purposes, or at least a mutually accepted direction (Grice, 1989: 26).

Grice identified the Cooperative Principle as a 'super principle' or a 'supreme principle' (1989: 368–369) that he generalized from four conversational 'maxims' he claimed discourse participants ordinarily follow. With a nod to Kant, Grice identifies the maxims as:

1. Quantity (give as much information as is required, and no more than is required)
2. Quality (do not say what is false or that for which you lack adequate evidence)
3. Relation (be relevant)
4. Manner (be clear, be orderly, and avoid ambiguity) (1989: 28).

Clear fulfillment of these maxims may be demonstrated in the following exchange:

A: Do you know where I can buy some petrol?
B: You can buy petrol at the garage right around the corner.

Let us assume that B is sincere and knowledgeable, and A finds the garage right away based upon B's advice. It is the case then that B's response to A's question follows the maxims completely, giving exactly the right amount of information (quantity), information for which B has the required evidence (quality), information that is directly connected to A's question (relevance), and information given in a fashion effectively and efficiently understood (manner).

But Grice knew that people do not always follow these maxims as they communicate. (What dull business conversation analysis would be if they did!) Rather, interlocutors can fail to fulfill the maxims in a variety of ways, some mundane, some inadvertent, but others lead to what most consider the most powerful aspect of Grice's CP: conversational 'implicature.'

Failures to Fulfill Maxims and Implicature

Grice describes four ways in which maxims may go unfulfilled in ordinary conversation. The first three ways are fairly straight forward. One might **violate** or **infringe** a maxim. This infringement is often done with the intention of misleading; for example, one might say, 'Patricia was with a man last night' as a way of making Patricia's routine dinner out with her husband seem clandestine. One might **opt out**, making it clear that one refuses to cooperate in a conversation for some reason; for example, one may be legally bound not to provide information one has. Or, one might encounter a **clash** of maxims, facing the choice of violating one maxim or another. For example, one may not be able to give all of the information required (quantity) because one does not have adequate evidence for the information (quality).

Most interesting is the final possibility for the non-fulfillment of a maxim: **flouting** or **exploiting** a maxim for the purpose of implicating information (implicature). This case is the one in which even an apparently uncooperative response illustrates discursive or linguistic cooperation. Recall the examples with which this article was introduced.

A: I am out of petrol.
B: There is a garage round the corner.

In this instance, we may claim, that B – at first blush – appears to break the maxim of relation. For what does a garage have to do with petrol? Since drivers are aware that garages sell petrol, it is not long before A realizes that B has not broken the maxim of relation at all; it is, in fact, instantaneous. B's point is directly relevant. B is being cooperative in both the colloquial sense and the specialized sense Grice applies to the term. Grice's Cooperative Principle makes sense of the speed with which A is able to process the usefulness of B's contribution. A assumes B is following the maxims and would thus not mention the garage unless it had petrol.

In the next scenario, however, the exchange, and thus the rational process by which A makes sense of B's contribution, is markedly different:

A: I am out of petrol.
B: (sarcastically) How nice that you pay such close attention to important details.

In this instance, B flouts the maxim of quality by stating as true something for which he has specific and immediate evidence is untrue. One likely implication of B's remark is that A is an idiot for not paying attention to such an important detail as having enough petrol in the car. If A feels the sting of B's remark, A and B have exhibited discursive

cooperation that resulted in an implicature directed to A from B (see **Maxims and Flouting**).

While one example hardly illustrates so many cases, Grice works out a number of possible forms of implicature: irony, metaphor, meiosis (understatement), hyperbole, social censure, deliberate ambiguity, and deliberate obscurity (for example, if one is trying to keep a secret from the children). In all of these cases, maxims are broken and the breaks result in specific information implied to and understood by the receiver of the utterance.

The power of the conversational maxims to describe rational processes by which speakers and hearers make sense of each other's utterances have energized many scholars of language and conversation across many fields. But, as the introduction to this article makes clear, the Cooperative Principle has not been free from serious critique.

Major Critiques of the Cooperative Principle

Problems with the Term 'Cooperation'

Despite the care with which he used the term "cooperation," Grice is regularly accused of promulgating a theory that assumes too friendly a spirit of communicative interaction among people. This charge is most commonly made in work outside of Grice's own field of linguistic philosophy. In effect, these detractors claim Grice is just too nice.

For example, Tannen (1986) claims that Grice's maxims of cooperative discourse can't apply to "real conversations" because in conversation "we wouldn't want to simply blurt out what we mean, because we're judging the needs for involvement and independence" (1986: 34–45). Tannen assumes that Grice's maxims are prescriptions that conversations must follow strictly in order to be considered cooperative. Cameron (1985) makes a similar case, taking issue with Grice's application of the term 'cooperation' to all discourse. Cameron is quite correct in her claim that – at least in the colloquial sense of the term – assumptions regarding the appropriateness of 'cooperative' behavior have dogged women for centuries. But Cameron demonstrates a reductive view of Grice's use of the term 'cooperation' when she describes Grice's CP as an 'inflexible' and 'unproductive' apparatus that provides yet another way for both 'chauvinists and feminists' to believe that 'whereas men compete in competition, women use co-operative strategies' (1985: 40–41). Grice's version of cooperation is more flexible and less dogmatic than these critics assume.

Others have gone so far as to claim Grice **advocated** cooperation among conversational participants,

believing Grice prescribed cooperation as the most effective way of engaging in meaningful communication with others.

Cooper (1982), interested in applying Grice to theories of written composition, claims that Grice advocates cooperation because

what enables conversation to proceed is an underlying assumption that we as conversants have purposes for conversing and that we recognize that these purposes are more likely to be fulfilled if we cooperate (1982: 112).

The notion that discourse participants cooperate with each other and that they do so out of a mutual benevolence is a misreading of Grice's position on cooperative discourse; but it is one that persists.

Grice himself acknowledged the difficulty some have had interpreting his use of 'cooperation.' As a final chapter to his 1989 book, Grice wrote a 'Retrospective Epilogue' in which he considered criticism his theories had engendered. It has already been related that here Grice acknowledged that his theory suffers from a perceived naïveté. To combat the criticism, Grice adds useful information about what counts as cooperative in discourse. First, he reminds readers of the sort of utterances he seeks to elucidate: voluntary talk exchanges that require some form of "collaboration in achieving exchange of information or the institution of decisions." And, he points out that within exchanges intended to produce information or determine decisions, cooperation "may coexist with a high degree of reserve, hostility, and chicanery and with a high degree of diversity in the motivations underlying quite meager common objectives" (Grice, 1989: 369). Even as adversarial an exchange as a hostile courtroom cross-examination would at least simulate adherence to the CP.

To further explain the sort of cooperation to which Grice refers, it might help to borrow a term from classical rhetoric. The ancient Greeks used the term 'Nomos' to indicate cultural practices that defined a group of people. Two closely related connotations of the term are useful for the present discussion: (1) 'the mores' of a given collective (Ostwald, 1969: 33); and, (2) customs "which are generally observed by those among whom they prevail" (1969: 36). Nomos is not necessarily an explicit, prescribed set of conventions, but rather a set of conventions that are brought into existence by the very fact that people ordinarily follow them, perhaps without even realizing they are following a set of conventions. When American youths visit Europe, the locals can spot them in an instant by their footwear; but, in the United States, sneakers are simply what young people ordinarily wear.

Nomos applied to conversation, then, is a set of conventions, or rules (or maxims) for talk according to

which a group of people ordinarily makes meaning. In the maxims, Grice believes he has found universal conventions that all people may regularly follow in their meaning-making talk exchanges. In order for such a set of conventions to function, a certain degree of at least tacit assent to those conventions is necessary. Thus, the term ‘cooperation’ is quite apt.

The crucial subtlety of Grice’s theory is this: interlocutors do not necessarily cooperate with each other; they cooperate with a set of conventions that allows each interlocutor to produce approximate enough meanings for communication to work. This form of cooperation is not necessarily benevolent at all; even the bitterest of verbal fights require linguistic cooperation to work.

The aim for Gricean conversation analysis – and thus the CP and the maxims – is not to advocate benevolent cooperation, but to prove the rationality of conversation. “...observance [of the maxims] promotes and their violation [except in the case of implicature] dispromotes conversational rationality” (Grice, 1989: 370).

Although many have claimed Grice’s writing on the CP is ambiguous and is on occasion inconsistent with terminology, this should not be said of Grice’s measured use of the term ‘cooperation.’

Precise readings of Grice’s writing on cooperation demonstrate that he rarely, if ever, describes interlocutors as **being** cooperative. Rather, he claims that interlocutors’ contributions to conversation are **cooperative**. The contributions are uttered in cooperation with a set of conventions for producing meaning. In this sense, we might think of a pair of interlocutors as each operating according to the dictates of a set of conventions (the maxims) and thus they are ‘co/operators’: two operators of discourse operating at once.

Consider also, Grice’s use of the term ‘dovetailed’ in describing the state of cooperative contributions to conversation (1989: 29). Dovetailed elements are placed within very close proximity to each other, maintaining the integrity of each separate element, but creating a stronger whole. Utterances remain utterances, but conversations take flight, implicating new meaning for hearers and speakers.

Problems with the Maxims: The Haphazardness of Communication and the Specificity of Maxims

The second major critique of the Cooperative Principle has been a topic of spirited discussion among linguistic philosophers since Grice first proposed it. Grice himself identifies the problem as resulting from the thought that communication is simply too “haphazard” to be described accurately as having a cooperative end. Some forms of communication are not

appropriately described by the CP. For example, as Grice puts it, “Chitchat goes nowhere, unless making the time pass is a journey” (1989: 369).

Grice suggests the problem is two-fold. First, he agrees with critics that the maxims appear less “coordinate” than he would prefer. The maxim of quality appears in some ways more definitive of information than the other maxims. And, the maxims are not independent enough: relevance, as will be shown, has been often regarded as containing the essence of the other maxims. Second, Grice’s selection of cooperation as the “supreme Conversational Principle” underpinning the rationalizing operations of implicature remains, to say the least, not generally accepted (1989: 371).

In his ‘Conversational maxims and rationality’ Kasher (1976), claims that cooperation is not a principle that accounts for all information conveyed by implicature because cooperation may be “contrary to [a speaker’s] interest” (1976: 241). Kasher offers the following example: Man A. is asked by Man B. “Who is going to marry your sister?” Man A., who knows the proper name of the intended, replies, “A peacock dealer.” Man A.’s reply, Kasher points out, does not satisfy the demands of full cooperation, and the CP, claims Kasher, cannot account for a situation in which there is no cooperation. As an alternative explanation for the operation of conversational implicature, Kasher poses the “Rationalization Principle,” which stems from the idea that Relevance (one of Grice’s maxims) is the only necessary element to explain a talk exchange. In a later work, Kasher renames his principle “the principle of rational coordination,” which states: “Given a desired basic purpose, the ideal speaker chooses that linguistic action which, he believes, most effectively and at least cost attains that purpose” (Kasher, 1977). Kasher’s well known critique thus began what has become ‘Relevance Theory,’ which is at its base a refinement of Grice’s earlier work (*see Relevance Theory*). (See below for references to other work on Relevance.)

Though in his final work he admitted some misgivings and offered minor refinements of his maxims of cooperative discourse, Grice, up until his death in 1988, defended his selection of the Cooperative Principle as the ‘supreme principle.’

Scholarship Influenced by the Cooperative Principle

Though critiques of the CP remain unresolved – and perhaps they always will be – there is nevertheless no denying that Grice’s CP has had a dramatic influence on discourse studies across disciplines. The CP can

probably not be considered definitive, but there is no denying it has proven quite generative.

Because Grice's Cooperative Principle has such cross-disciplinary appeal, any survey of work influenced by it is almost certainly incomplete. The sketch here is intended to acquaint the reader with some applications of major importance and to give readers a richer understanding of the depth and breadth of the influence Grice has had. (For more citations and commentary on work influenced by Grice's CP, see Lindblom, 2001.)

Grammar

Grammarians frequently view literal or sentence meaning as more important than any individual's intended meaning in making an utterance. Thus Chomsky, for example, has critiqued Grice's CP for being unprincipled (1975: 112) and has complained that Grice's approach to language study is behaviorist due to his focus on utterer's intention (Suppes, 1986: 121). Other grammarians influenced by Chomsky have used similar logic to critique the CP as too concerned with context.

Suppes, whose essay is an excellent synthesis of grammar studies using Grice, argues that these grammarians assume an even more closely rule-bound language governance, making their claims essentialist. Further, he argues, that Grice's CP is useful precisely because it is so context dependent. Chomsky's positivism is not an issue in a Gricean analysis because Grice's work "bring[s] out the importance of context" (Suppes, 1986: 124).

Neo-Gricean Pragmatics

Grice's influence is most apparent in a branch of linguistic study that has become known among some as Neo-Gricean pragmatics. Scholars in this field have greatly revised Grice's maxims of cooperative discourse in a variety of interesting ways, but they have maintained the basic direction of Grice's work, especially in regard to the concept of conversational implicature. Huang (1991) usefully surveys a great deal of scholarship from well known scholars in this area, including Atlas, Levinson, Sperber and Wilson, Leech, and Horn.

As mentioned previously, Kasher developed a specific focus on one of Grice's maxims, thus establishing the field of Relevance Theory. Sperber and Wilson have also generated an important Relevance Theory, theirs influenced by Fodor's theory of cognitive modularity. According to Huang, Sperber and Wilson believe "one is always maximizing the informational value of contextual stimuli to interpret the utterance in a way which is most consistent with

the Principle of Relevance" (Huang, 1991: 303). Along with texts by Kasher and Sperber and Wilson, important developments in Relevance Theory may also be found in Grandy and Warner (1986) and Tsohatzidis (1994).

More recently, a special issue of *Journal of Pragmatics* has focused exclusively on Gricean themes in pragmatic analysis. Although he resists the notion of a school of 'Neo-Gricean' approaches, the journal editor has nevertheless gathered a collection of papers that illustrates that Grice's CP and maxims are ideas that "shook the world of language study in the past century, and continue to move and inspire today's research" (Mey, 2002: 911). The special issue includes essays focused on social roles in Japan, maxim confluence among multi-lingual code-switchers, academic writing, and other current approaches to Gricean pragmatics.

The CP is not only applicable across cultures, it is also possible to use Gricean analysis to examine a 'theme' in discourse. For example, much interesting work is underway in the pragmatics of humor (for example, Attardo, 2003).

Politeness Theory

Politeness theorists use Grice's CP specifically to examine the ways in which maxims are exploited to indicate some special status of the hearer. For example, a lawyer would answer a judge, "Yes, your honor." The 'your honor' breaks the maxims of quantity – as surely the judge is aware of her title – but including the words 'your honor' implies the speaker's understanding that the judge holds a greater position of authority.

For a valuable survey of Politeness Theories, see Fraser (1990). In this piece Fraser examines politeness theories posited by Lakoff and by Leech, and he explains that both of these theories rely heavily on Grice's CP, though Lakoff reduces the maxims by two and Leech increases the number by six. The most influential Politeness Theory was developed by Brown and Levinson (1987).

Brown and Levinson's work is primarily influenced by Goffman, but they also claim "Grice's theory of conversational implicature and the framework of the maxims that give rise to such implicatures is essentially correct" (1987: 3). Goffman's influence may be seen in Brown and Levinson's concentration on the concept of 'face wants.' Their politeness theory examines the ways in which speakers and hearers use conversational implicature to fulfill the 'face wants' of higher-status participants in conversation. Like the CP itself, Politeness Theory is certainly not free from critique, but it has resulted in fascinating analysis and has generated much spirited debate.

Question Processing

Several works in the area of question processing have developed from Grice's Cooperative Principle. Questions and questioning patterns can result in implicatures regarding politeness, status, and authority, and they operate according to conventions that many have build upon Grice's maxims. Singer provides a useful assessment of the study of question processing in all of its stages: question encoding, question categories, selection of answering strategies, memory search, comparison, and response (1990: 261). He identifies 'response' as the category for which Grice's CP is the most powerful.

Most interesting in 'response' is Lehnert's theory of secondary questions. According to Singer, "If asked 'Are there oil wells in Manitoba?' a simple 'no' would appear rather blunt. Instead, in keeping with Grice's 'maxim of quantity' and Lehnert's theory of secondary questions, it is more appropriate to hypothesize the next logical question and answer, 'There are a few, but there is not much oil east of Saskatchewan.'" (Singer, 1990: 273).

Gender Studies

Though above we single out some scholarship in gender studies for applying superficial accounts of the CP, there is excellent scholarship in the field that has used Grice's CP and maxims to examine behavioral and status differences between women and men. Brown, using the Politeness Theory she developed with Levinson, has used Grice to examine the socio-political situations of women in non-Western cultures (1990). Rundquist and Michell have looked at men's and women's use of conversational strategies in western culture.

Rundquist uses Grice to confront the "popular belief that women's speech is more indirect than men's" (1992: 431). She finds that men more frequently than women flout maxims to implicate information. Some of the purposes she identifies for which men tend to implicate information include to "give direction to their children," to "put themselves down as well as to tease others," "to be humorous," "to show themselves off to their best advantage in conversation," and perhaps most significantly for a study of gender, "to avoid direct confrontation" (Rundquist, 1992: 447). Michell (1984) questions if women often flout maxims to implicate information. She determines that women are far more likely to simply lie to protect themselves from verbal and physical abuse in a misogynist culture. For example, imagine a woman missed a meeting because she had painful menstrual cramps and because she had an important report to finish. This woman would be far more

likely to claim she missed the meeting because of the report, leaving out the mention of cramps, even if the report was not even close to being the primary reason for her absence; her omission is an opting out, not an implicature (Michell, 1984: 376).

Teacher Research and Pedagogy

Studies in teacher research have approached Grice's Cooperative Principle for two important purposes: (1) to examine the discourse of the classroom situation; and (2) to establish effective pedagogical strategies.

Three valuable works serving the first purpose may be found in Edwards and Mercer (1987), Kleifgen (1990), and McCarthy (1987). The first two works focus closely on the ways in which the educational scenario highlights the need for listeners to fill in propositions implicated by speakers. Edwards and Mercer examine the ways in which children become more and more proficient in these skills through their educational training. Kleifgen suggests that teachers should look for the points in classroom discourse when students begin to predict the outcomes of teachers' questions so quickly that it is clear the students are ready to move on to a higher level of difficulty.

McCarthy's essay – probably the finest treatment of the CP from a pedagogy scholar – traces the development of a college student as he writes for his composition, cell biology, and poetry classes. Examining both the student's written assignments and the teachers' detailed responses to them, McCarthy uses Grice's CP to determine what is required for this student to cooperate as a writer in each class and whether or not he was successful. In McCarthy's judgment, the student was successful as a student because he was able to determine "what counted as 'cooperation'" in each of his classes (1987: 249). Thus, McCarthy uses the CP in a flexible, context specific manner consistent with Grice's own descriptions of it.

Other scholars with an interest in writing instruction have used Grice for productive ends. Though they are too likely to read Grice's CP as describing a benevolent, cooperative relationship between writer and reader, Cooper (1982; 1984) and Lovejoy (1987) have used the CP to positive effect in college writing classes. Lovejoy's very practical revising template using the maxims is especially useful for college students learning to write more sophisticated texts.

Professors of literature have also found Grice's CP of use in articulating abstract themes from literature. Pratt's (1977) work is probably the best known, but for a fascinating reading of Beckett's *Waiting for Godot* using Gricean analysis, see Gautam and Sharma (1986).

Conclusion

A cross-disciplinary examination of how Grice's Cooperative Principle has been put into practice clearly indicates that the CP has had tremendous appeal and influence. It is precisely the CP's flexibility and context-dependent nature that makes it of such broad value. However, that same flexibility and context-dependence has also generated a fair number of critiques that cite lack of specificity and a too-relativistic application to discourse. Thus, it seems, the CP's strength is also its weakness. Certainly a great diversity of scholars have found the Cooperative Principle of Discourse and its attendant Maxims of Conversational Cooperation useful as analytical tools toward a variety of ends. It is doubtful, however, that the notion of 'cooperation' among discourse participants will ever be universally accepted.

Coreference: Identity and Similarity

Y Huang, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

Defining Coreference

Coreference can in general be defined as the phenomenon whereby two or more anaphoric or referential expressions denote, or refer to, the same entity in the external world. This can be illustrated by (1).

- (1) John said that he had won two Olympic gold medals.

In (1), if the anaphoric pronoun *he* refers to what its antecedent *John* refers to, then there is a relation of coreference obtaining between them; *he* is thus said to be coreferential with *John*. In contemporary linguistics, including generative grammar, coreference between two or more anaphoric or referential expressions in a sentence or discourse is usually marked by using identical subscript letters, as in (2) or numbers, as in (3).

- (2) John_i said that he_i had won two Olympic gold medals.
(3) John₁ said that he₁ had won two Olympic gold medals.

Another common way of saying that *he* and *John* are coreferential is to say that they are coindexed. On the other hand, in (1) if *he* does not refer to what *John* refers to, then the two anaphoric/referential expressions are disjoint in reference. Disjoint in reference is typically marked by using different subscript letters, as in (4), or numbers, as in (5).

- (4) John_i said that he_j had won two Olympic gold medals.
(5) John₁ said that he₂ had won two Olympic gold medals.

Identity

From a truth-conditional, semantic point of view, the anaphoric relation exhibited in (1) is called referential anaphora (e.g., Huang, 2000: 5). A referential anaphoric expression refers to some entity in the external world either directly, as in (6), or via its coreference with its antecedent in the same sentence or discourse, as in (1). In the latter case, as already mentioned, the referentially anaphoric expression refers to what its antecedent refers to, thus they are of referential identity.

- (6) (Referent in the physical context, and with selecting gesture)
He's the robber!

Similarity

We move next to types of anaphoric relations that may be said to indicate some kind of anaphoric or referential dependency other than referential identity.

Bound-Variable Anaphora

Sentence (7) is an example of bound-variable anaphora.

- (7) Every child₁ wishes that he₁ could visit the land of Lilliput.

Generally speaking, a bound-variable anaphoric expression does not refer to any fixed entity in the external world, as can be shown by sentences such as (8) below.

- (8) Nobody₁ thought that he₁ would wish to live with the giants of Brobdingnag.

But it is interpreted by virtue of its dependency on some quantificational expression in the same sentence or discourse, thus seeming to be the natural language counterpart of a bound variable in first-order logic. As indicated by (7) and (8), the bound-variable anaphoric expression and its quantificational antecedent can be coindexed, but they are not considered to be coreferential.

One interesting characteristic of bound-variable anaphora is that different languages afford their speakers different types of anaphoric or referential expressions to encode such a dependency, (cf. Huang, 2000: 6). For example, to express a bound-variable anaphoric relation between a matrix subject and an embedded subject, while English normally allows neither gaps (or empty categories) nor reflexives, Serbo-Croatian allows gaps (or empty categories), Marathi allows reflexives, and Chinese allows both.

- (9a) Gaps or empty categories (Serbo-Croatian cited in Huang, 2000: 6)
svaki student misli da ce Ø
every-M-SG student thinks that will
dobiti desetku.
get A
'Every student thinks that he will get an A.'
- (9b) Pronouns
Every actress said that her career has been a roller coaster ride.
- (9c) Reflexives (Marathi, cited in Huang, 2000: 6)
sarvāānaa₁ vaatta ki aapan₁ libral aahot.
everybody believes that self liberal is
'Everybody believes that he is liberal.'

- (9d) Gaps and reflexives (Chinese)
- | | | | | | | |
|--------|----|--------------|-----|------|----|------|
| mei | ge | ren | dou | shou | Ø/ | ziji |
| every | CL | person | all | say | | self |
| xihuan | | zhongguocai. | | | | |
| like | | Chinese food | | | | |
- ‘Everybody says that he likes Chinese cuisine.’

Note next that crosslinguistically bound-variable anaphora occasionally can also be encoded by repeating the same lexical NP.

- (10) Of every ritual bronze that was found in the tomb, it was subsequently discovered that the bronze belonged to the Chinese Northern Song élite.

Finally, as noted in Kempson (1988) and Huang (1994: 292), examples of the following kind can also have a bound-variable interpretation. On such a reading, the supervisor is interpreted as each Ph.D. student’s supervisor. Of particular interest here is that this bound-variable interpretation is obtained only by virtue of the addition of the pragmatic inference that every Ph.D. student characteristically has a supervisor.

- (11) Every Ph.D. student thinks that the supervisor is intelligent.

E-Type Anaphora

Somewhat related to bound-variable anaphora is E-type anaphora, also known as *donkey* anaphora, first discussed by Geach (1962: 128). It is called E-type anaphora in memory of the late Oxford philosopher Gareth Evans after Evans (1977). A classical example of E-type anaphora is given in (12).

- (12) Every farmer who owns a donkey beats it.

For technical reasons, an E-type anaphoric relation is neither pure referential anaphora nor pure bound-variable anaphora, but appears to constitute a unified semantic type of its own (Evans, 1977). The main reason why it is neither pure referential anaphora nor pure bound-variable anaphora is this: the antecedent of the anaphoric pronoun *a donkey* is variable-bound by a quantificational expression *every farmer*, but unlike in the case of pure bound-variable anaphora such as (7), the antecedent does not syntactically bind the anaphoric pronoun, because the antecedent does not c-command the anaphoric pronoun. Put differently, in E-type anaphora, the anaphoric expression falls outside the scope of its binder (see also Heim, 1990; Kamp and Reyle, 1993; de Swart, 1998: 127–130).

Anaphora of Laziness

The following is a classical example of anaphora or pronoun of ‘laziness’ (e.g., Karttunen, 1976).

- (13) The man who gave his paycheck to his wife was wiser than the man who gave it to his mistress.

Anaphora of laziness is so-called because it exhibits neither a referential anaphoric relation nor a bound-variable anaphoric relation. Rather, it functions as a shorthand for a repetition of its antecedent, which supplies the descriptive content for the anaphoric expression. In other words, it is a device for a repeated occurrence of the linguistic form, rather than the truth-conditional content of its antecedent. This can be illustrated by a consideration of (13). In (13), the referent of *it* is the paycheck of the second man rather than the paycheck of the first man. There is thus no coreferential relation between *it* and *the paycheck*. Anaphora of laziness is considered as a case of the semantically defined type of identity of sense anaphora, that is, anaphora in which the anaphoric expression and its antecedent are related in terms of sense. It is on a par with N-bar-anaphora, as in (14), and arguably with the sloppy reading of VP-ellipsis, as in (16b) (see Huang, 2000: 131–156 for further discussion of VP-ellipsis).

- (14) Mary’s favorite tenor is Pavarotti, but Jane’s Ø is Carreras.

- (15) John loves his wife, and Peter does, too

- (16a) Strict reading
John likes John’s wife, and Peter loves John’s wife.

- (16b) Sloppy reading
John likes John’s wife, and Peter loves Peter’s wife.

Identity of sense anaphora contrasts with the semantically defined type of identity of reference anaphora, that is, anaphora in which the anaphoric expression and its antecedent have identical referent, as (2) illustrates.

Bridging Cross-reference Anaphora

Bridging cross-reference anaphora is used to establish an association with some preceding expression or antecedent in the same sentence or discourse via the addition of background assumption (e.g., Clark, 1977; Huang, 1994, 2000). What is tacitly bridged is typically the information that is not structurally retrievable either from the sentence or discourse that triggers the inferential process. A typical example of bridging cross-reference is given below.

- (17) John walked into a church. The stained glass windows were magnificent.

In (17), the anaphoric expression is *the stained glass windows*, and its antecedent is *a church*. The pragmatically inferred background assumption is that the church John walked into has stained glass windows.

As pointed out in Huang (2000: 249), bridging cross-reference anaphora has three characteristic properties:

1. The anaphoric expression, which is usually a definite NP, must occur in the appropriate context of its antecedent, which is usually an indefinite NP,
2. There is some semantic and/or pragmatic relation between the anaphoric expression and its 'antecedent,'
3. The anaphoric expression and its antecedent do not stand in a strictly coreferential relation. Rather, they are linked to each other via the addition of some pragmatic inference (see Huang, 2000: 249–253 for further discussion).

Other interesting cases of anaphoric or referential dependency other than referential identity may include split antecedence and overlap in reference.

Counterfactuals

S Barker, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Counterfactuals are a class of conditionals, or *if-then* statements. They are interesting because they are instances of a semantically significant class of sentences, conditionals, and because of their intimate connections to modality, laws of nature, causation, dispositions, knowledge, perception, and other concepts, all of which are of central philosophical concern.

Counterfactuals are those *if*-sentences that have a modal auxiliary as main consequent verb and have in their antecedent and consequent clauses a backward shift of syntactic tense relative to notional tense that renders those clauses incapable of self-standing assertion (see Dudman, 1994). Some instances:

- (1) If Osama had not existed, George would/might/could have created him.

- (2) If Osama were to strike, George would defeat him.

Paradigmatically, counterfactuals are uttered in the knowledge that they have false antecedents, but this is not a characterizing mark. They may be issued when their antecedents are believed to be merely improbable. Furthermore, *indicative* conditionals may be asserted with known false antecedents; consider (3).

- (3) If Bill Clinton was bald, no one knew about it.

There is some debate about where to draw the line between counterfactuals and, more broadly, subjunctives and indicative conditionals (see Jackson, 1987; Dudman, 1994; Bennett, 2003). This mainly concerns the status of future open conditionals like (4), which, as Dudman (1994) pointed out, has the same syntactic tense shift found in counterfactuals and has a consequent modal auxiliary.

- (4) If Clinton goes bald, everyone will know about it.

Another issue is whether counterfactuals have truth conditions. There are strong arguments that indicatives, like (3), do not but that they do require a probabilistic assertability condition semantics (see Adams, 1975; Edgington, 1995). Unification of *if* indicates that counterfactuals should be treated similarly. But just how to provide a probabilistic semantics for counterfactuals is far from obvious (see Edgington, 1995; Barker, 1999).

Let us assume from now on that counterfactuals do have truth conditions. The central problem of counterfactuals is devising a noncircular specification of their truth conditions. Philosophers have tended to concentrate on the *would*-conditionals, conditions of the form *If P had been the case, Q would have been* (abbreviated $[P > Q]$), the assumption being that other counterfactuals, such as *might*-conditionals (*If P had been the case, Q might have been*, abbreviated $[P \Diamond \rightarrow Q]$), can be analyzed in terms of the former (for proposals, see Lewis, 1973, 1986c; Stalnaker, 1981).

There are broadly two forms of analysis of counterfactual truth conditions: *metalinguistic* analyses and *possible worlds* analyses. Both are said to be inspired by the idea, in Ramsey (1990 [1929]), that we evaluate a conditional by adding the antecedent to our stock of beliefs and adjusting for consistency, to determine if the consequent is in the resultant state.

The older approach is the metalinguistic one. Possible worlds are currently the entrenched view. Lewis (1973) argued that they are equivalent, which is open to dispute (see Barker, 1999).

Metalinguistic Approaches

On the metalinguistic approach, counterfactuals are like condensed arguments – roughly, P and laws of nature L plus facts cotenable with P (legitimate factual premises) entail, or probabilize, Q :

$$(P > Q) \text{ is true} \equiv \{P + \text{Cotenable factual premises} + L\} \rightarrow (\text{probable}) Q$$

The challenge for metalinguistic theories is (i) to define in a noncircular way the conditions for A 's being cotenable with P and (ii) to fashion a conception of law. Goodman (1965) famously found both of these to be insuperable challenges.

Goodman argued that the extensionally correct specification for a premise A to be cotenable with P is as follows:

$$A \text{ is cotenable with } P \equiv (P > \text{still } A)$$

The conditional $(P > \text{still } A)$ is a *semifactual*: a counterfactual with a true consequent A , expressing that

P is causally benign with respect to A , as in *If the match had been struck it would still have been dry*. Goodman argued that the truth conditions of a semifactual are as follows:

$$(P > \text{still } A) \equiv \sim(P > \sim A) \ \& \ A.$$

But this introduces circularity into the analysis, since we have defined conditions of cotenability in terms of counterfactuals.

The second challenge – finding some acceptable analysis of natural laws – is to provide an explanation of why some generalities support counterfactuals and others do not. Goodman despaired of finding that mysterious counterfactual supporting feature. The current conception is that the problem of law is less acute, since irreducible modalities are now more palatable (for discussion of some of the issues, see Jackson and Pargetter, 1980; Sober, 1988).

After Goodman, various metalinguistic theories attempted to deal with the problem of cotenability, e.g., Pollock (1981), but were not successful. Kwart (1986) represented a very sophisticated breakthrough. Central to his analysis was the idea that counterfactuals presuppose indeterminism for their literal truth, since they involve a conception of reality's branching off from a time t_0 prior to the antecedent time t_p and developing through a *scenario of transition* to P – and orderly, lawful development of reality to P . Kwart showed that Goodman's cotenability condition was extensionally incorrect, since his truth conditions for semifactuals were wrong and he analyzed cotenability by using the notions of positive causal relevance and causal irrelevance, which in turn were reduced to probabilistic relations. Kwart's theory, however, could not capture certain cases (see Belzer, 1993).

Barker (1999) provided an improvement over Kwart with a quasialgorithmic approach to solving the problem of cotenability; Barker's approach invoked causal or more broadly connective relations. The truth conditions of a semifactual relative to a scenario S leading to P are given thus, where p_i is an event in S :

$$(P > \text{still } A) \equiv \sim(P \Diamond \rightarrow p_i \text{ causes } \sim A) \ \& \ A$$

To determine $(P > Q)$ relative to a scenario S , we need to find an instantiated law-based generality ($G1$) linking P to Q via true A . To determine A 's cotenability, we need to evaluate $(P > \text{still } A)$. To determine that, we need to determine $(P \Diamond \rightarrow p_i \text{ causes } \sim A)$. This can be evaluated directly if there is no instantiated law-based causal generality ($G2$) linking P , factual premise B , and the possibility of p_i causing $\sim A$. If there is no ($G2$), $(P \Diamond \rightarrow p_i \text{ causes } \sim A)$ is false, $(P > \text{still } A)$ is

true, and so $(P > Q)$ is true. If there is a (G2), then we ask if the might-conditional cotenability condition $(P \Diamond \rightarrow \text{still } B)$ is true, and that leads to a line of inquiry similar to that for $(P > \text{still } A)$. The recursion is bound to terminate at some stage and provide a determinate answer about the truth values relative to S of the counterfactuals in the procedure. We do the same evaluation of $(P > Q)$ for all the scenarios leading to P . A noncircular determination of $(P > Q)$'s true results. Unlike Kvart's account, Barker's approach can be extended to deal with probabilistic counterfactuals.

Possible Worlds Approach

Lewis (1973) proposed these truth conditions in terms of possible worlds and similarity relations:

$(P > Q)$ is true iff some (accessible) world where both P and Q is more similar to our actual world @, overall, than is any world where P is true and Q is false.

Stalnaker (1968) offered a variant that assumes that there is a unique closest P -world to the actual: Lewis's does not.

Lewis (1973) gave some evidence that this general approach captures the basic logic of counterfactuals – explaining the failure of transitivity, antecedent strengthening, etc. (Metalinguistic theories can do similarly through relativizing entailments to scenarios of transition.)

According to Lewis, would-counterfactuals have two readings: *forwardtrackers* and *backtrackers*. Forwardtrackers are meant to be those counterfactuals that are used in analyzing causation and that capture the sense in which the future depends causally on the past. Backtrackers carry information about the causal in the opposite direction.

Lewis (1986c) offered R as the criteria governing the similarity metric that determines relative similarity of possible worlds in the case of forwardtracking counterfactuals. R :

- i. It is of first importance to avoid big, widespread, diverse violations of law.
- ii. It is of second importance to maximize the spatio-temporal region throughout which perfect match of particular fact prevails.
- iii. It is of third importance to avoid even small, localized, simple violations of law.
- iv. It is of little or no importance to secure approximate similarity of particular fact, even in matters that concern us greatly.

The result of application of R is meant to be that the closest P -worlds to the actual @ will be worlds

that diverge from @ at a time t_0 not too long before t_p , at which point a small miracle of divergence occurs, and thereafter develop in a law-governed way. *Miracle* has purely a technical meaning: miracle relative to the laws of @, not with respect to the laws of the P -worlds, which remain unbroken. Laws of nature require nothing stronger than a Humean account. Laws are simply statements that feature in the most economical description of the pattern of matters of fact in a world in which perfectly natural properties are picked out.

Unfortunately, there is strong evidence that Lewis's analysis fails for deterministic cases (see Elga, 2000; Hausman, 1998), because the *de facto* temporal asymmetries of physical determination that Lewis thought provide the basis for counterfactual dependency of future on past, do not in fact deliver that result. There are strong reasons to think it fails for indeterministic cases and in particular for counterfactuals such as (5), which depends for its truth on a chance outcome: the coin's landing heads.

(5) If I had bet on heads I would have won.

If, following clause (iv) of R , approximate agreement of fact after t_p counts for nothing, Lewis's theory deems (5) false, because (I bet heads)-worlds in which the coin lands heads and I win and (I bet heads)-worlds where it lands tails and I lose are equally similar to the actual world. If we allow approximate agreement of fact to count, then it is still not obvious why (5) would come out true. Change the situation so that the end of the world will occur if I win, then (5) comes out false, even though my betting has no causal influence on the coin. It seems global similarity has absolutely nothing to do with the evaluation of (5). Indeed, it can be argued that causation is essential (see Barker, 2003). Lewis's analysis fails.

Some Issues

A pure analysis of counterfactuals without invoking causation looks dubious. There is real concern that Lewis's (1986b) project of a counterfactual analysis of causation will be circular (see Barker, 2003). A more general issue is the direction of counterfactual dependency. To date, both metalinguistic and possible worlds treatments have failed to provide an adequate account. Why does counterfactual thought involve divergence from past to future rather than the other way around? (For one interesting discussion of these matters, see Price, 1996.)

Creativity in Language

E V Clark, Stanford University, Stanford, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Speakers change languages all the time because their needs in using language change. One major type of change appears in the words people use and the meanings they assign to them. Speakers construct new words to add to their vocabulary, to talk about new trends and developments in society (*boycott*, *sabotage*, *space-station*) and to take into account technical and scientific innovations (*aviation*, *gene-splicing*, *parallel processing*, *flash-memory*). And they discard terms that no longer serve any purpose – some that are rarely used today include *barouche*, *jeroboam*, *wringer*. This is why dictionary making is endless. Lexicographers track how speakers change their words over time, and the vocabulary of a language is never fixed. Speakers continually add new terms for new categories and adjust existing meanings to take account of extensions (often metaphorical) and also shifts introduced by the addition of other words in the same domains, for example the shift from *guitar* to

acoustic guitar under pressure from the contrast with *electric guitar*. Some new terms that speakers coin are taken up by others, eventually by the speech community as a whole, and so become part of the current conventional vocabulary. Other coinages are used once only, and then vanish again. In all of this, speakers effectively assign an indefinite number of meanings to a finite number of forms in the language they use. They do this by combining compositional meanings with pragmatic inferences dependent on the context, and so continually extend the resources available in new ways.

Coining Words

When speakers coin words, they do so to convey some meaning that is not covered by the meanings of existing words in the vocabulary. For example, a fairly new verb like *to farmer*, meaning 'play the role of farmer (without being a real farmer)' contrasts with its near-neighbor *to farm*, which designates the activity of being a (real) farmer. In constructing the forms of new words, speakers follow the rules

for word formation in their language. In English, for example, they can have recourse to novel compound nouns (e.g., *the circle-group* vs. *the oval-group*, to describe two groups distinguished by insignia), to derived nouns and adjectives (e.g., among recent nouns *a peace-keeper*, *the polluter*; among recent adjectives *internationally minded*, *safety-challenged*), and to denominal verbs (*to medal* in an Olympic event, *to land* a plane even on water, *to e-mail* the message) (e.g., Clark and Clark, 1979; Marchand, 1969). Other languages may draw on a slightly different repertoire of options: French, for example, like other Romance languages and like Hebrew, makes little use of compounding and relies much more extensively on derivation for new words (e.g., Depecker, 2001; Guilbert, 1975). In making use of such word-formation patterns, speakers generally choose the most productive forms – the patterns currently favored by speakers – for the meanings to be expressed (Clark, 1993). This productivity of a pattern can change over time. For example, the Verb + Noun pattern used for forms like *pinch-penny*, *toss-pot*, and *pick-pocket* lost its productivity after this pattern acquired a generally negative connotation in the 1700s. Other patterns, such as N + V-er for agentive and instrumental meanings (as in *tomato-grower*, *cheese-cutter*, *picture-painter*), may remain highly productive over many years. But speaker preferences for particular patterns and affixes can shift, and this typically results in changes in the productivity of particular word-formation patterns and suffixes over time (Dubois, 1962).

Coinages are ubiquitous in everyday speech and in many kinds of writing. While temporary or nonce uses come and go, other coinages may be regulated in that language academies often make recommendations about new terminology. This happens in many countries for new fields of enquiry where a language academy may simply keep track of the coinages that speakers come up with as the Swedish Academy does, or make active recommendations about the terms to use in specific domains, as in France or Israel (Berman, 1997; Clark, 1993). Most language academies tend to focus more on written than on spoken forms of the target language, yet it is in their everyday speech that people continually renew their language.

Children Coin Words, Too

Children start learning what the options are for constructing words – the ways to put together stems and affixes to express different meanings – from the earliest stages of acquisition. They may make use of some productive options in their language from as young as age 2. Like adults, they coin words

to add to their vocabulary and so extend their range in talking about the objects and events around them. In doing this, they apply patterns observable in the established vocabulary in constructing new words: nouns such as *sleepers* for ‘pyjamas’, *climber* for ‘ladder’, *reacher* for ‘someone who can reach a long way’, and *drummer* for ‘drummer’, are typical of the forms constructed by 2- and 3-year-olds. They also construct new adjectives such as *windy* for ‘blown by the wind’, or *walky* for a path ‘one can walk along’, as well as new verbs like *crack out* for ‘hatch’, *oar* for ‘row’, *piano* for ‘play the piano’, or *untight* for ‘loosen’.

Young children have much more limited vocabularies than adults at first, so they may coin many words illegitimately. That is, they coin a word to convey a meaning for which there is already a conventional term. They may come up with forms like *farsee-er* for ‘telescope’, *to car* for ‘to drive’, *to rug* for ‘to vacuum [a rug]’, or *to needle* for ‘to mend’ (Clark, 1993). These coinages are pre-empted by the conventional terms adults use for those meanings, and children give them up as they learn the appropriate terms. As children get older, they become more adept at coining words where there are no existing words with just the meanings they wish to express. They become sensitive to the relative productivity of specific patterns and affixes, and, like adults, favor more productive over less productive options. Also like adults, they continue to attend to transparency in meaning – 2-year-olds prefer a compound like *magic-man* over a derived form like *magician* in which the term *magic* is less discernible. They also attend to simplicity in form – 2-year-olds prefer making the least possible change when they construct a new word form.

Language Revival

The 20th century saw the revival of several languages. The best known of these perhaps is Modern Hebrew, adopted by early Jewish settlers in the Near East as their everyday language from the 1890s on. After the establishment of the state of Israel in 1948, Modern Hebrew was adopted as the national language. Speakers of Hebrew then had to create hundreds of new words for all the everyday things they needed to be able to talk about in modern life, from tractors and engine parts to postal systems and school-leaving exams. They borrowed extensively from other languages, through loan translations, and they coined words for whatever they needed in agriculture (including fish farming, raising turkeys, and meat packing), plumbing, child rearing, schooling, and marketing, as well as in politics, economics,

and science (Blau, 1981; Bolozky, 1999; Ravid, 1995). Israel also set up an Academy of the Hebrew Language to make recommendations about new vocabulary as speakers expanded the existing resources from historical and ritual varieties of Hebrew. The Academy continues to make recommendations today, often lagging behind speakers who take the initiative before any official recommendation appears.

The Irish Gaelic language in Eire faced a similar challenge as the government pushed for its revival as people's everyday language (Watson, 2003; Wright, 1996). Reintroducing Irish in geographic areas where it had not been spoken for several generations, and adding the range of vocabulary needed so it could indeed be used for all everyday purposes presented a formidable challenge. Speakers who had retained their Irish tended to be from rural areas and rural occupations, so, as in Israel, the need for new vocabulary in many social and scientific domains was extensive. Welsh faces similar challenges in maintaining itself as a full everyday language (Aitchison, 2000), as does Scots Gaelic and many other minority languages that often received little official support.

Other languages currently undergoing similar attempts at revival include a number of Australian aboriginal languages and American Indian languages (e.g., Amery, 2000; Hinton and Hale, 2001). In many cases, linguists have been called on to help devise writing systems and help prepare teaching materials, so the languages in question can be (re-)introduced into the community at the nursery school level and up, within the local school system. Few of these revivals, though, have gone as far as Hebrew or Irish Gaelic in building up vocabularies adequate for all facets of modern life. Yet this infusion of vocabulary may be a vital ingredient for endangered languages: speakers' willingness to invigorate the language with new words may well be essential if a language is to remain viable.

Syntactic Units and Combinations

Do speakers construct entirely original, new utterances on each occasion, using syntactic rules to put together new combinations of terms, or do they rely more on ready-made phrases, chunks, and idioms? Within generative grammar, the traditional claim has been that speakers can generate innumerable utterances that they have never produced before (e.g., Chomsky, 1986). That is, speakers are assumed to construct original syntactic combinations, each one built from scratch according to the rules. But does that claim really capture what goes on in most interactions? As native speakers, people have access to a large repertoire of words, phrases, idioms, and

constructions, many of them very frequent in everyday speech.

So an alternative view is that speakers typically build their utterances from ready-made routines and a limited set of constructions. In relying on formulaic uses and routines in language, speakers tailor them to their needs by inserting words, idioms, and phrases that result in new combinations within a construction, and even thereby stretch the meaning of a construction. One reason for doing this is to take advantage of the chunks of language people store in memory (Bolinger, 1976; Fillmore, 1979). This view is consistent with recent work on the myriad syntactic forms, often designated as peripheral to a language, where 'the rules fail' (Culicover, 1999). Recent approaches have tackled these as exemplifying cases where a construction-based, rather than a rule-based, approach may prove more explanatory of how speakers use language. The hypothesis is that when people talk, they work with constructions and formulaic chunks where they can fill variable slots to express specific meanings on different occasions (e.g., Kay and Fillmore, 1999).

Extending Language in New Directions

Creativity in language – stretching meanings and coining words – is also a form of play, one delighted in by many writers who have stretched their language to new limits. In James Joyce's *Ulysses*, Keri Hulme's *The Bone People*, or Tibor Fischer's *The Thought Gang*, for example, each writer extends the meanings of existing words through new juxtapositions and figurative uses. And each writer coins many new words to express new meanings. Poets like Gerard Manley Hopkins (*daylight's dauphin, dapple-dawn-drawn Falcon*, or *golden grove unleaving*) or Dylan Thomas (*the windfall light, the round/ Zion of the water bead/ And the synagogue of the ear of corn*) are often major innovators in language, stretching meanings and adding new forms for new meanings. And many playwrights also extend the uses of a language. Here English speakers probably owe their greatest debt to Shakespeare whose plays are the source of innumerable metaphors, figures of speech, and phrases generally taken for granted until we are startled to hear them fresh-minted in a speech from one of his characters.

The extent to which speakers exploit established and novel figurative uses of language in everyday speech is unclear, but research on language processing shows that readers and listeners readily interpret new uses, figurative uses, and extensions of existing meanings without difficulty (e.g., Gerrig, 1993; Gibbs, 1994).

In summary, speakers are creative in their language use because language is never a precise map of what they wish to convey. Languages do not all select the same elements in a scene to encode, but they select enough to evoke events and their participants. Yet this mapping leaves unmentioned many a detail, as well as many changes in society itself. Speakers, writers, poets, and children remedy such gaps by stretching the meanings of the terms they have and by constructing new words for the new meanings they wish to convey.

Data and Evidence

C Schütze, University of California at Los Angeles,
Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

This article surveys the major kinds of data used by linguists, focusing on the properties that bear on their usefulness in linguistic analysis – what they can serve as evidence of, and what sorts of assumptions underlie their interpretation. Linguistic data is divided herein along two dimensions: its origin, i.e., the method or technique by which it was obtained, and its kind, i.e., the phenomenon from which it was drawn. Although these dimensions are in practice not fully orthogonal, the separation helps make the issues clearer.

Sources of Data

Corpora

‘Corpus data’ can be characterized as (a collection of) preexisting samples of language – that is, language that was originally produced for some purpose other than directly answering linguists’ questions.

The contents of corpora provide evidence that has not been biased by the researcher. Similarly, they can provide samples of language produced when the speakers/writers were not consciously reflecting on the form of their utterances. (This point is not trivial: Labov (1975) documented that speakers who denied that they would ever produce a certain construction went on to do so spontaneously during the very same interview.) Corpora may bring to attention phenomena that would not otherwise have come to mind. Because they typically contain extended passages of contiguous language, they supply evidence about phenomena that cannot be studied in isolated words or sentences, e.g., how referents are identified throughout a narrative or discourse. They also provide virtually the only kind of evidence about languages that are no longer spoken.

The ability to search a corpus by computer and calculate statistics on its contents provides detailed quantitative data – for example, about the relative

frequencies of different forms or constructions – that cannot be directly obtained by other methods discussed in this section. For example, corpus data are increasingly being used to show that constructions that tend to sound artificial and awkward when presented as isolated examples in linguistics articles nonetheless may occur and sound natural in everyday language situations. A further benefit to corpora of spontaneous language is reflected particularly in studies of acquisition and speech production: One can find ‘errors’ in such corpora, whether systematic productions by children that are not possible in the adult language or sporadic speech errors (slips of the tongue).

The kind of evidence that a corpus can supply is limited, however: for a given form of interest (morpheme, word, construction, etc.), it can tell us whether or not that form occurs, and if so, how frequently and in what contexts. What such occurrences and nonoccurrences are evidence of has no general answer. Nonoccurrence in particular is a challenge to interpret: it could imply that the form is not possible in the language, that the intended message never called for its use, or that it is inappropriate to the genre/register/modality or some other property of the corpus. Absence from even a large corpus constitutes at best a weak piece of evidence for ill-formedness.

Taking the **presence** of a form in a corpus as evidence that it is part of the language might seem more straightforward, but here too there are caveats, since by definition there is no way to further question the person who produced the utterance to begin with. It is paramount to know the exact origins of the corpus. For example, many texts of dead languages have been copied by people who did not themselves speak the language in question; they might have (knowingly or accidentally) altered the text while copying it. Similarly, when searching the Internet, it is hard to be certain whether the source of a given utterance is a native speaker. Furthermore, to obtain evidence that is relevant to linguistic theories, one typically also needs to know what an attested form means. This may or may not be determinable from the corpus.

For practical reasons, most corpora today are collections of written rather than spoken language. Written language in general admits of ill-formedness that would not occur in speech, arising from the writing and editing process. In the composing or editing of text it is possible to make piecemeal alterations to a sentence without being forced to reread it to verify that it still hangs together as intended (as well as, of course, making typographical errors). Editing may also introduce structures that would not be producible in real time, such as multiple center-embeddings. Thus, a single instance can scarcely count as evidence of anything whatsoever. The typical course of action is to count: if a form of interest occurs enough times in a corpus (there is no standard for how many times is enough), it can be assumed not to be the result of a random editing or copying error; however, the confounds noted above could still apply. (A ‘confound’ is a factor that systematically affects the outcome of a study but is not deliberately manipulated by the researcher. In the present case, the outcome could consist of the distribution of words, sentence types, etc., in a corpus. This could be systematically affected by, for example, the editing process, which may be totally outside the scope of the researcher’s interests if these involve spontaneous language production. What the researcher is manipulating might be anything that varies in spontaneous production, e.g., sentence length or who is speaking.)

Grammaticality Judgments

So-called ‘grammaticality judgments’ involve explicitly asking speakers whether some particular string of words is a possible utterance of their language, with an intended interpretation either implied or explicitly stated. (Analogous judgments can be sought for materials larger or smaller than a single sentence.) Grammaticality judgments provide evidence about the status of phenomena that occur so rarely in spontaneous language use that we could not learn about them from studying corpora; in particular, they distinguish possible from impossible utterances among those that have never been naturally produced. Grammaticality judgments sometimes demonstrate knowledge of language in speakers whose behavior on other tasks does not evince the same degree of knowledge. For example, Linebarger *et al.* (1983) showed this experimentally for people with agrammatic aphasia, and it has been reported (e.g., Berko and Brown, 1960) that children will sometimes reject an adult’s faithful repetition of an utterance they have just produced, apparently realizing that their own productions are not hitting the intended target. Another circumstance where speakers’ judgments may diverge from their own usage, noted

above, arises particularly when the phenomenon under study involves forms identified with social status. A way in which one can try to deal with such cases is to distance the judgment from the speakers themselves, by not asking, “Would you say this?” but rather, “Have you heard people say things like this?” or “Do you know anyone who talks like this?”

Although there are strings of words that seem unequivocally completely well-formed (*Mary saw John*) and strings that seem completely ill-formed (e.g., *Fred the the this*), most strings of linguistic interest lie in a vast gray area between these two extremes. For this reason, simply eliciting yes/no grammaticality judgments is of limited value. Two solutions are to elicit responses on a five- or seven-point scale (as is typical in psychology), or to elicit relative judgments that compare minimal pairs of sentences. The notation used to indicate the status of sentences has evolved to allow numerous gradations of well-formedness to be indicated, but even so, the **relative** status of examples is primarily what is being described; the same annotation does not always convey the same absolute level of well-formedness.

In some cases it is difficult to replicate relatively agreed-upon judgments of linguists while testing naïve subjects with no linguistic training (e.g., Gordon and Hendrick, 1997). Partly for this reason, and partly for sheer convenience, linguists rely heavily on other linguists for judgment data on some languages. Some consider this undesirable (cf. Spencer, 1973). Valian (1982) made a case in favor of using such ‘expert’ judgments, based on analogy to another domain: she noted that wine tasting, for example, relies on the acquired ability to detect subtle distinctions that inexperienced wine drinkers simply cannot make. Wine experts detect these subtleties easily, reliably, and consistently from one person to the next. Her suggestion was that linguists have the same skills with language. One practice that is clearly undesirable, however, is for investigators to use **their own** judgments as their primary evidence.

The nature of grammaticality judgments has sometimes been characterized with reference to traditions in psychology that might lead one to worry about the wisdom of using them as evidence in linguistics: they have been described as “introspective” judgments or “intuitions,” but neither of these terms applies accurately (Carr, 1990; Schütze, 1996). They have more in common with the responses in psychophysics experiments, having the character of sensations or reactions to stimuli, or else reports about mental states (e.g., pain) or social-psychological judgments for which there is no objective external measure to compare them to, e.g., judging the seriousness of various crimes or the prestige of various occupations.

There is also no basis for the occasionally encountered view that grammaticality judgments are somehow related to competence, while spontaneous production and comprehension data are related to performance; all are behaviors – hence performance data – but all can in principle provide evidence (indirectly) about competence (cf. Smith, 2004). For these reasons, Schütze (1996) argued that ‘acceptability reactions’ would be a more accurate and less confusing term, removing reference to the ambiguous and loaded notion ‘grammar,’ but the dominant usage is unlikely to be overturned.

Fieldwork

Much of our linguistic data is vanishing before our very eyes: at least 20% and perhaps as many as 50% of the languages spoken in the world, as of the year 2000, were not being learned by children and will thus cease to be spoken at all by 2100, unless dramatic changes occur (Krauss, 1996). This state of affairs has led to the suggestion that linguists should devote greater attention to documenting and helping to preserve endangered languages, which typically involves fieldwork with native speakers. Field linguists have a great influence over what kinds of evidence can subsequently be constructed from their data, by virtue of how they record the data (e.g., how detailed their transcriptions are), what forms they choose to elicit, and which of these they disseminate. Eliciting meaningful data is a specialized skill and art: one must, for example, avoid inventing utterances in the speaker’s language and simply asking for good/bad judgments about them as one would do with a fellow linguist, because for various sociological reasons speakers tend to over-accept ungrammatical forms. At a minimum, one must verify that speakers can repeat the utterance back; if not, it probably is not really part of the language they speak (Munro, 2000).

Data gathering for ethnographic and sociolinguistic purposes, including dialectology, is also typically considered a type of fieldwork; it mainly involves language as it is naturally spoken when people meet and interact in their daily lives, rather than in a formal elicitation situation. Here, the issues that affect the collection and interpretation of data include a range of variables that are known to influence the way people talk, e.g., the identity of the speaker and addressee (sex, age, social status, education, ethnic heritage, power relationships) and properties of the situation (number of conversants, physical setting, level of formality, topic of conversation, social goals such as establishing group solidarity). To interpret this kind of data, one must face what Labov (1972) called the ‘observer’s paradox’: when people know

they are being observed or recorded, their way of speaking changes, but we want to study how they speak in situations when they are not being observed. A common attempt to minimize this problem involves introducing maximally engaging subject matter to draw speakers’ attention, for example, by asking about emotional topics such as a life-threatening event, or how the world has changed since they were young.

Experiments

It has sometimes been suggested that claims made exclusively on the basis of grammaticality judgment data, do not necessarily bear on how the human language faculty actually works, unless their ‘psychological reality’ has been tested using some other sort of data, typically a formal experiment. This view belies a misunderstanding: grammaticality judgments are themselves data about human behavior that need to be accounted for; they are not intrinsically less informative than, say, reaction-time measures (in fact, one might argue the opposite). The elicitation of grammaticality judgments can itself be seen as a behavioral experiment, albeit one whose generally casual nature may leave it susceptible to certain kinds of confounds. (These can be a result, for example, of the limited number of types and tokens of items tested, the small number of participants questioned, or lack of randomized order of presentation.) Nevertheless, in this section, ‘experiment’ will refer to traditional formal experiments.

The most direct behavioral experiment one can perform to assess the status of sentences or other forms is essentially a more rigorous version of grammaticality judgment collection, typically done using a written questionnaire with a multivalued response scale. In the case of syntactically well-formed strings whose possible meanings are at stake (e.g., sentences with multiple quantifiers), a truth value judgment task may be appropriate for adults, just as it is for children (Crain and McKee, 1985). Beyond experiments that ask participants for their reactions explicitly, a large variety of experimental paradigms used in psychology can be employed to assess participants’ language in more indirect ways. These generally involve a trade-off between reducing the influence of conscious reflection about language on the data and making response measures more difficult to interpret as evidence *vis-à-vis* linguistic issues. There have also been experimental paradigms developed expressly for (psycho)linguistic purposes, e.g., the so-called Wug test (Berko, 1958), lexical decision, self-paced reading, and naming. In some domains, experimental data collection can occur during ‘normal’ language-processing activities (e.g., from eye movements

during reading), where the only ‘abnormality’ involves the physical restrictions imposed by the equipment.

Recent years have shown the promise that we might learn about the workings of language by direct measurements from the brain. Techniques used in this way have included event-related potentials (ERP), functional magnetic resonance imaging, positron emission tomography, and magneto-encephalography. In addition to expensive equipment, these all require special training in the use of the hardware and in statistical techniques for analyzing the data. While some of these techniques may provide a relatively fine-grained characterization of the parts of the brain that are most involved in processing certain aspects of linguistic stimuli, this localization is not terribly helpful as evidence about the particulars of linguistic structure. More provocative have been suggestions (mostly in the ERP literature) that the grammatical status of certain classes of stimuli (e.g., word or sentence types) might be reflected in characteristic patterns of activity (e.g., Neville *et al.*, 1991). For example, it has been claimed that syntactic vs. semantic anomalies have distinct signatures, and even that violations of different grammatical constraints show different patterns. Interpretation of these claims is still open to debate, however, in that it is not established whether a full range of superficially diverse sentence types that by hypothesis share a common grammatical property (e.g., violating Subjacency) have a detectable commonality in brain activity; if it turns out that each kind of ungrammaticality (e.g., extraction from a subject island versus an adjunct island vs. a complex NP island) produces a different ERP pattern, the value of this kind of data for theoretical purposes may be limited. The hope driving this line of research, however, is that if we can find reliable brain signatures for clear cases of certain linguistic properties, we can then compare them to brain measures in reaction to unclear cases and take the brain data as evidence on how to treat those unclear cases.

Kinds of Data

Language Acquisition and Creolization

In addition to informing the study of language acquisition in its own right, data from children acquiring language may be relevant more generally as evidence about human language. By elucidating the ‘starting state’ of the language-acquisition process, it may yield insights into language universals and unmarked values of parameters, on the assumption that the initial state embodies these. Via the course of development, child

grammars may arise that never surface as adult grammars, providing the only opportunity to study those grammars directly. In a similar but more dramatic vein, creolization provides evidence for the noninput-driven nature of knowledge of language, since in this case it is ‘invented’ (unconsciously) by children when there is no robust language present in the input. If one takes the view that language is a mental construct internal to the individual speaker–hearer, then in both normal acquisition and creolization situations, learners are doing the same thing: determining which of their possible internal grammars is most compatible with the ambient speech. What is unique to the emergence of a creole is the fact that the ambient speech is not being generated by any other human’s internal grammar. As a result it might be compatible with a great many of the learners’ possible grammars, or with none at all; in either case the learners must make ‘decisions’ on some basis other than what they are hearing. Thus, even more strongly than for other acquisition data, it is thought that creoles may provide fairly transparent evidence for the defaults of grammar.

Second Language

The language of nonnative speakers may illuminate how native language learning depends on special properties of childhood that do not persist over a lifetime, e.g., so-called ‘critical period’ effects. It may also inform us about which properties of a language should be identified with a single locus of knowledge, e.g., a parameter. As a hypothetical example, consider speakers of languages that have V-final clauses and P-final adpositional phrases. We could pursue the question of whether a single ‘head parameter’ is responsible for ordering in all lexical projections by asking whether such speakers make the same sorts of word-order errors with V as with P when learning a language that is V-initial and P-initial. Adult second-language learners also potentially provide data about language acquisition that are not obtainable from child acquirers due to independent limitations on cognitive ability, memory, attention span, articulatory control of the vocal tract, and so on. Of course it remains to be shown to what extent adult and child acquisition are parallel; in particular, it is hotly debated whether the starting state for second-language acquisition is the universal default from which infants begin, the grammar of the first language, or something else.

Bilingualism

Bilingual (or multilingual) speakers can provide a unique kind of data for linguists, in that they allow

crosslinguistic comparisons that control for all factors other than language (cognitive abilities, cultural experiences, etc.). (This is true also of concurrent bilingual acquisition by children, given the mounting evidence that children separate the systems of their two languages early and easily.) Bilingual speakers additionally have a unique behavior, (intrasentential) code switching, that is constrained in ways that could bear on the grammar. Furthermore, given sufficient understanding of the ways in which two linguistic systems connect with each other and with a (presumably) common cognitive system, new experimental avenues may be opened up.

Language Disorders

Linguistic data from people with language disorders is often (but not uncontroversially) taken as evidence of how language works in unaffected speakers. This may seem paradoxical, since the presence of a disorder *ipso facto* indicates some divergence from the way language normally works. Nevertheless, for many disorders it is believed by numerous researchers that selective loss of language functions reflects the way language is implemented in the brain for affected and unaffected speakers alike, and hence can tell us which aspects of language depend on the same subsystems and which are relatively independent. This assumption might seem justified in the case of brain injuries, as opposed to congenital disorders, but even then, the brain can adapt to such changes, so that a person's speech may actually reflect the loss of some function **plus** an atypical mechanism developed in response to that loss. The fact that data from language disorders typically involve small numbers of speakers, often single case studies, provides further cause for using them cautiously as evidence about human language in general.

Performance Errors

Speech errors have proven to be a rich source of data on the organization of linguistic representations in the mind/brain, as well as on the time course of language production. Certain kinds of speech errors can be experimentally induced, but these are limited and their ecological validity is questionable. Most of the work in this area has traditionally been based on observational collection of spontaneously produced slips assembled into sizeable databases. More recently there has been growing concern about the degree of bias in data collected this way – linguists tend to write down errors that have interesting properties, while letting relatively mundane ones pass by unrecorded. This is widely believed to lead, at the least, to a bias in the relative proportions of error types represented in informally gathered corpora. As a consequence,

some researchers advocate culling errors only from recorded language samples that can be scrutinized exhaustively until no more errors can be found. What this kind of data gains in quality it loses in quantity: the amount of time required for this procedure would have been prohibitive for amassing the collections of tens of thousands of speech errors that were needed to establish basic generalizations. Those errors were produced, and certainly the kinds that occurred in reasonable numbers should be taken as evidence about human language.

Typology and Historical Change

Much can be learned from the range of attested variation across languages, as well as systematically unattested patterns. In addition to providing evidence for the range of possible human languages, such data provide evidence as to which properties of language necessarily covary and which are independent. For this purpose both 'macroparametric' variation (large-scale differences among typologically very different languages) and 'microparametric' variation (minimal differences between linguistically, and usually also geographically, very close languages) is relevant. The kinds of changes that occur in the same language over time can be seen as a special case of the latter, with the further benefit that historical records may allow us to identify the triggers for certain changes, providing evidence for causal connections between language input and grammatical development.

General Remarks

Variability

A problem linguists face every day is how to explain apparently conflicting data about a language, most commonly situations where different speakers of 'the same language' or even 'the same dialect' report different reactions (e.g., different well-formedness judgments) to identical stimuli. On the one hand, those who take a cognitive perspective are investigating what is in the mind/brain of each individual ('I-language'), rather than an abstract object out in the world ('E-language'), so there would be no contradiction in finding that speakers do not have identical I-languages. This could happen because the language input that speakers were exposed to during acquisition was not identical, or because their brains are not identical, i.e., universal grammar is subject to individual variation.

On the other hand, it is worrying if too many such differences are found, because it might be a sign that the judgments are reflecting, in heterogeneous ways, individual differences **outside** the

grammar. The conundrum arises because any data collected from a single individual are susceptible to random confounds; the best way to eliminate such confounds is to consider multiple speakers and hope for convergence. An important emerging finding stressed by Cowart (1997) is that while the well-formedness of a particular sentence might be rated (say) 5 out of 7 points by one participant and 2 out of 7 points by another, there is much less individual variation in the **patterns** of responses – that is, in how sentences rate **relative** to one another. (Cowart also stressed the need to run appropriate statistical tests to determine this.) This is the reason why linguists are primarily concerned with contrasts, say between a sentence marked ‘??’ (barely grammatical/marginally possible) and one marked ‘*’ (ungrammatical/impossible), but not about how good or bad ‘??’ really is in any absolute sense.

Thus, to the extent that numerous speakers show the same pattern of data, the odds of this pattern being the result of some random source diminish rapidly, and it can be taken as solid evidence. However, there is no way to apply the opposite logic: unique judgments of a particular speaker could be good evidence about their idiolect, but it is harder to be certain of this; certainty increases to the extent that the same speaker behaves consistently on different occasions and tasks. More generally, because no single kind of data is perfect, an efficacious approach to linguistic investigation is to seek converging evidence from a wide array of types of data whenever possible.

Data, Evidence, and Theory

There are an essentially limitless number of facts about languages that one could, in principle, document. Data collection therefore always involves selecting – either implicitly or explicitly – certain facts to use as data while ignoring other facts. Often, linguists collect data because they have a theoretical issue they want to pursue and are seeking evidence that will bear on it. To take a syntactic example, linguists studying a particular language might want to know whether a construction they have identified involves (in Government-Binding terms) ‘object control’ versus ‘raising-to-object’ (e.g., *I ordered them to find the answer* versus *I believed them to know the answer*). They are seeking evidence that the crucial noun phrase (*them*) originates as an argument of the ‘upstairs’ verb or evidence that it originates in the ‘downstairs’ clause. They will therefore want to look for data (which might come from grammaticality judgments, if a speaker is available, or from a corpus) on such things as the possibility of the crucial noun phrase being an expletive, an entailment

relation with related sentences lacking the complement clause, synonymy under downstairs passivization, etc. The choice of data to be collected is thus driven by the theory, which in turn determines the questions that are to be answered on the basis of empirical evidence. Even when linguists are not explicitly pursuing any theory, their choices of data to collect are guided by hypotheses or hunches about how languages tend to work, which aspects are relatively unpredictable, and so on, as well as possibly the immediate pragmatic goals of the task. So, if instead the aforementioned linguists had been writing the first grammar of this language, collecting these particular pieces of data might not have occurred to them at all, or if it had, it might have been considered of too little importance relative to other things that such a grammar should include.

A final point to be made about the relationship between data in its raw form and its application as evidence can be illustrated with a well-known, though often misrepresented, example from the early years of generative grammar: the ‘derivational theory of complexity’ (DTC). The idea was that a transformational model of syntax would be independently supported if one could find evidence from language processing for the application of transformations, assuming that a sentence should take longer to process if deriving it required applying more transformations. Data on this point were fairly easy to collect, and in some cases *prima facie* contradicted the predictions of the DTC: for example, passives without *by*-phrases took less time to process than their longer counterparts with *by*-phrases, while the former were supposed to be derived from the latter by one additional deletion transformation; the (full) passive versions of some sentences were sometimes faster to process than their active counterparts – e.g., when the active structure involved center-embedding and the passive converted this to right-branching – while passives were always supposed to be derived from actives by one additional transformation. At the time, these data were taken as evidence against the DTC, which was generally abandoned for several decades; it was concluded that transformations did not necessarily literally apply during the processing of a sentence, either because transformations were the wrong theory of syntax or because syntactic theory as a competence model could not be expected to have reflections in real-time language behavior.

But the leap from the data to what it was evidence of was a mistake. The error involved overlooking a *ceteris paribus* assumption: more transformations should imply more processing time **all else being equal**, but in the crucial cases just mentioned, there is good reason to think that all else was not equal.

For example, processing time surely has a component that increases with the number of words in a sentence (just keep adding instances of the word *very*, for example), which could explain the *by*-phrase result. And center-embedding plausibly puts a burden on short-term verbal memory that could slow language processing in general, independent of any other properties of a sentence, which could explain the passives that were faster than actives. Thus, while the collected data are evidence about the overall processing load differences between pairs of transformationally related sentences, the hypothesis being tested concerned just processing load due to the application of the extra transformation. It therefore called for different data: the processing load differences between sentences that differed in the number of transformations applied, but **not** on any other property that might reasonably be expected to affect processing load. Only the latter kind of data should count as evidence bearing on the DTC.

De Dicto versus De Re

E Eaker, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Philosophers of language and linguists often distinguish between *de re* and *de dicto* readings of certain locutions. For example, take the sentence, ‘Juan believes that the man who wrote *Platform* is Belgian.’ As a rough initial characterization, to read this sentence *de re* is to read it as saying that Juan has a belief *about the man himself* – namely, Houellebecq – that he is Belgian. Juan need not be thinking of Houellebecq as the author of *Platform* in order for the sentence – read *de re* – to be true. Juan may have said, ‘Michel Houellebecq is Belgian,’ or, pointing at Houellebecq, ‘That man is Belgian.’ The important thing is that Juan has a belief about that man, however he is characterized.

In contrast, to read this sentence *de dicto* is to read it as saying that Juan has the following belief: *the man who wrote Platform is Belgian*. Here, ‘the man who wrote *Platform*’ is a crucial part of the content of Juan’s belief. For this *de dicto* report to be true, it is not even necessary that Juan knows who wrote the book *Platform*. Indeed, he may believe that the man who wrote that book is Belgian for reasons that have nothing to do with any information he has obtained about the man Houellebecq.

There are many conflicting ways of characterizing this distinction, and so even a preliminary characterization is controversial. There have been three key elements in traditional discussions of this distinction: syntactic representation, semantic interpretation, and metaphysical import. These three elements are often tied together in such discussions, and it is the aim of this article to provide the reader with tools for keeping them distinct.

Usually, the distinction between *de re* and *de dicto* readings is made for complex sentences, where one sentence, such as ‘Dimitri’s plane is late,’ is embedded in the context of what is often called a sentential-complement-taking clause or a sentential operator. Some sentential operators are ‘Juan believes that...,’ ‘It is not the case that...,’ ‘Howard denies that...,’ and ‘It is possible that...’

Take, for example, the sentence, ‘Juan believes that Dimitri’s plane is late.’ It is commonly thought that there are two readings of this sentence – a *de re* and a *de dicto* reading. On the *de dicto* reading, the embedded sentence is, in a certain important sense, treated as a syntactic and semantic unit. The embedded sentence taken as a whole is treated as a key player in the

semantics of the larger sentence in which it is embedded. To understand the *de dicto* reading then, we must understand what a sentence as a whole can contribute semantically.

Gottlob Frege (1948) proposed that the meaning of a sentence is the thought that it expresses. Bertrand Russell (1905) also was concerned with the thoughts or ‘propositions’ that sentences are used to express. Though Russell talked of propositions as the objects of belief, he thought that they could, in principle, be composed of ordinary objects and properties. In this he differed from Frege, who could make no sense of the idea that an object could be apprehended directly in thought. Frege argued that all thought about objects is mediated by representations of those objects – such representations or senses of expressions occur in Fregean thoughts or propositions, not the objects themselves. So, as key ingredients of a semantic theory, Fregean thoughts and Russellian propositions look like very different sorts of entities. In some writings, Russell seemed closer in his views to those who think sentences express (actual or possible) facts or states of affairs. Contemporary discussions of sentence meaning often involve the question of whether propositions must be ‘structured’ or can be represented as sets of possible worlds (often ‘centered’ with respect to an individual).

In summary, on a *de dicto* reading the embedded sentence is treated as a syntactic and semantic unit. Its semantic value as a whole plays a key role in the semantics of the sentence in which it is embedded – whether this semantic value is taken to be a thought, a proposition, a fact or state of affairs, or an abstract set theoretic entity.

Let us continue with the *de dicto* reading of the sentence, ‘Juan believes that Dimitri’s plane is late.’ If you think, as did Frege, that sentences express thoughts, you will think that this sentence relates Juan to the thought content, *that Dimitri’s plane is late*, and says that Juan believes *that*. If ‘Dimitri’s plane is late’ is embedded in the context of ‘It is not the case that...,’ the embedded sentence might be taken to express the proposition *that Dimitri’s plane is late*. The whole sentence could then be interpreted as the claim that this proposition is not true. If we embed the sentence, ‘Dimitri’s plane is late,’ into the context of ‘It is possible that...,’ this could be interpreted as the claim that the state of affairs represented by the embedded sentence is a possible state of affairs.

These readings, which focus on the embedded sentence and the thought, proposition, fact, or state of affairs it represents, are in contrast with *de re* readings of the same sentences. On a *de re* reading of the sentence, ‘Juan believes that Dimitri’s plane is late,’

Juan is said to believe *of* Dimitri's plane – of that very thing – that it is late. Philosophers, philosophical logicians, and linguists have found various ways of emphasizing the *de re* reading by using different syntactic forms – and often very awkward ones. Applied variously to the sample sentences above, the 'rephrasing' strategy might yield the following: 'Dimitri's plane is believed by Juan to be late,' 'Dimitri's plane is possibly late,' 'Dimitri's plane is such that it is fortunate that it is late,' and 'Howard denies, of Dimitri's plane, that it is late.'

The difference between the *de re* reading and the *de dicto* reading might not strike the reader as important and may be difficult to grasp, even with these reformulations. It becomes apparent, however, when we recognize the distinction between opaque and transparent contexts (or, less theoretically neutral, intensional and extensional contexts.) Consider the sentence, 'Juan believes that Dimitri's plane is late.' Suppose that Pamela Anderson is on Dimitri's plane, though Juan has no idea that this is the case. If so, then Dimitri's plane is also Pamela Anderson's plane. However, would we want to say that Juan believes that Pamela Anderson's plane is late? Contexts that do not allow substitution of co-designative expressions without change in truth value are called opaque. They are also called intensional contexts by those who, inspired by Frege, think that linguistic expressions (including sentences) have both an extension and an intension. According to a Fregean theory, the intension of a sentence is the thought it expresses, and the extension of a sentence is its truth value. What then accounts for the opacity of the sentence, 'Juan believes that Dimitri's plane is late'? That is, why can we not substitute 'Pamela Anderson's plane' for 'Dimitri's plane'? A Fregean would say it is because 'Juan believes that...' is an intensional context – the expressions occurring in this context contribute their intension (thought content) to the semantics of the whole, not their extension (e.g., the plane itself that is being referred to by the two expressions).

However, this is not the whole story for the sentence, 'Juan believes that Pamela Anderson's plane is late.' Russell, for example, recognized a *de re* reading of the sentence. On the *de re* reading, this sentence does not say that Juan believes the proposition or thought content *that Pamela Anderson's plane is late*. It says that Juan believes, of a certain thing, namely a certain plane, that it is late. This plane happens to be Pamela Anderson's plane, Dimitri's plane, and the plane flown by Captain Marshall and First Officer O'Hare. However, on the *de re* reading it does not matter how we refer to the plane, so long as we refer to the right plane. If Juan has a belief about a

thing, then it does not matter how we refer to that thing, so long as we manage to refer to it and to assert correctly what it is that Juan believes about it. Read *de dicto*, 'Juan believes that Dimitri's plane is late,' is opaque, as the substitution of co-designative expressions may not preserve the truth value of the sentence. Read *de re*, it is transparent. Any way of referring to the plane will preserve the truth of the sentence.

Though he used different terminology, Russell (1905) represented the two readings by means of the notion of scope. If the definite description, 'Dimitri's plane,' occurs within the scope of the sentential operator, then it occurs within an opaque context and the whole sentence is to be read *de dicto*. To represent the *de re* reading, Russell put the definite description outside the scope of the sentential operator, where it occurs transparently or extensionally, which means that the substitution of any co-designative (co-extensive) expression will preserve truth. We might gloss the two readings that result from the permutation of the relative scope of the sentential operator and the definite description as follows:

Giving widest scope to the sentential operator to represent the *de dicto* reading:

Juan believes that: Dimitri's plane is late.

Giving widest scope to the description to represent the *de re* reading:

Dimitri's plane is such that: Juan believes that: it is late.

Complex sentences that talk about the beliefs and other psychological attitudes of people are not the only types of sentences that allow for both *de re* and *de dicto* readings. For example, consider the sentential-complement-taking clauses typically called modal operators. Examples of modal operators are 'It is possible that...' and 'It is necessary that...' Consider this sentence, 'It is possible that Dimitri's plane is arriving 15 minutes late.' Read *de dicto*, it is supposed to be understood as the claim that the proposition expressed by the embedded sentence, 'Dimitri's plane is arriving 15 minutes late,' is possible. (When philosophers say that a proposition is possible, they usually mean that though it may not actually be true, it expresses a state of affairs that could have been true or is true in some possible world.) So, even supposing that Dimitri's plane is on time, it could very well have been late – if there was bad weather, congestion on the runway, or the like.

Now, suppose that Dimitri's plane is in fact the only plane that is on time this afternoon. Could we not therefore say, 'It is possible that the only plane that is on time this afternoon is arriving 15 minutes late,' substituting the phrase, 'the only plane that is on time this afternoon,' for the co-designative (co-extensive)

‘Dimitri’s plane’? If the resulting sentence is read *de dicto*, it would seem to claim that the following is a possible state of affairs: The only plane that is on time this afternoon is arriving 15 minutes late. However, this is not a possible state of affairs, because being the only plane that is on time precludes arriving 15 minutes late. If we are reading this sentence *de dicto*, we cannot substitute a co-referring expression for ‘Dimitri’s plane’ without changing what the sentence says and possibly changing its truth value as a result. So, ‘It is possible that...’ seems to be an opaque context too, just as is ‘Juan believes that...’

However, just as ‘Juan believes that...’ allows for a *de re* reading, so does ‘It is possible that...’ If we were to read the modal sentence *de re* – as stating of a certain plane, the very plane that as a matter of fact happens to be the only plane to arrive on time this afternoon – that it is possible that *that plane* should be arriving 15 minutes late, then it does seem to be true. All planes, even planes that happen to arrive on time, are subject to being delayed by 15 minutes. How we refer to the plane does not matter when the claim is a *de re* possibility claim, a claim about what is possible for a particular plane. *De re* modal claims, just as do *de re* claims about Juan’s beliefs, allow truth-preserving substitution of co-designative expressions. This is in contrast to reading the possibility claim *de dicto*, where what is claimed is that a certain proposition or state of affairs is possible. On a *de dicto* reading it matters whether the embedded sentence is ‘the only plane to arrive on time this afternoon is arriving 15 minutes late’ or ‘Dimitri’s plane is arriving 15 minutes late.’ As with belief statements, it has been customary to represent the *de dicto* and *de re* readings of modal sentences by means of Russell’s device of scope:

Giving widest scope to the sentential operator to represent the *de dicto* reading:

It is possible that: the only plane to arrive on time this afternoon is 15 minutes late.

Giving widest scope to the description to represent the *de re* reading:

The only plane to arrive on time this afternoon is such that: it is possible that: it is 15 minutes late.

Notice that one of the sentential operators mentioned in the introduction – ‘It is not the case that...’ – does not create an opaque context. Suppose we read the sentence, ‘It is not the case that John’s uncle is on the plane,’ *de dicto*. That is, we read it as stating that a certain proposition – *that John’s uncle is on the plane* – is not true or as stating that a certain state of affairs does not obtain. Suppose John’s uncle is also Dave’s uncle and Saima’s uncle, and so we substitute ‘Dave’s uncle’ for ‘John’s uncle’ and get this sentence, ‘It is not

the case that Dave’s uncle is on the plane.’ It seems that no matter how we refer to John’s uncle, the truth value of the sentence as a whole is not going to change. If the proposition expressed by ‘John’s uncle is on the plane’ is false, then the proposition expressed by ‘Dave’s uncle is on the plane’ is likewise false; if the state of affairs picked out by ‘John’s uncle is on the plane’ does not obtain, then neither does the state of affairs picked out by ‘Saima’s uncle is on the plane.’ Unlike ‘Juan believes that...’ and ‘It is possible that...’, the sentential operator – ‘It is not the case that...’ – does not seem to create an opaque or non-extensional context.

If that is the case, what is the difference between the *de dicto* reading of the sentence and the *de re* reading in this instance? Suppose we read the original sentence *de re*, as stating of John’s uncle, that it is not the case that he is on the plane. If we are just talking about *that man* (who happens to be John’s uncle, Dave’s uncle, and Saima’s uncle) and saying of him that he is not on the plane, then we can use any way of referring to him that we like. This follows as a matter of course from the *de re* reading. However, we have seen that, though it is forbidden to substitute co-designative expressions in certain *de dicto* contexts, making that substitution here does not affect the truth of what is said. If the difference between the *de re* and *de dicto* readings does not seem to make a difference, then why should we distinguish the two in cases where the operator in question does not seem to create an opaque context?

Here is where it becomes very important to distinguish between the notion of scope – which involves the structural relations among quantifiers, sentential operators, and other linguistic expressions – and the semantic interpretations of complex sentences that scopal disambiguations may or may not be thought to represent. So far we have been using examples where the embedded sentence includes a singular referring expression, such as ‘Dimitri’s plane’ and ‘the only plane to arrive on time this afternoon.’

Yet, consider complex sentences that contain quantifier phrases, such as ‘someone,’ ‘every passenger,’ and ‘most planes.’ The sentence, ‘Juan believes that someone is responsible for the mistake,’ can be read in two ways, usefully disambiguated as follows: (1) ‘There is someone (in particular) whom Juan believes to be responsible for the mistake,’ said when Juan has specifically blamed Geoff; and (2) ‘Juan believes that someone (or other) is responsible for the mistake,’ said when Juan has scoffed at the idea that the mistake was a result of a random computer glitch. The difference between the two readings could be explained as a result of a structural ambiguity concerning whether the quantifier or the operator has widest scope. This is how we represented it above. Alternatively, some have

suggested that the ambiguity should be explained as the result of an ambiguity in the quantifier phrase itself, which might arguably be thought to allow for a ‘particular someone’ or a ‘someone or other’ reading. Likewise consider this sentence, ‘Every robber jumped into a car.’ This also seems to allow for the following two readings, represented by permutations of scope. The first reading is, ‘Every robber is such that there is a car such that that robber jumped into it.’ This would be true if, for example, every robber jumped into a different car. Contrast that reading with, ‘There is a car such that every robber jumped into it,’ which would be true only if every robber jumped into the same car.

In closing, the ambiguities that arise from the interaction of quantifiers with other quantifiers, and from the interaction of quantifiers with sentential-complement-taking phrases, can often be represented by means of the notion of scope (Montague, 1974). In a systematic theory of syntax and the logical structure of sentences, one may wish to acknowledge scopal ambiguities even when the results of scopal disambiguation are logically equivalent. In contrast, the *de re/de dicto* distinction for certain types of ambiguous sentences has typically involved a more robust semantic characterization of the distinct readings that result from disambiguation – even when these distinct readings are represented by means of a structural disambiguation, as above. This can be explained in part historically. The *de re/de dicto* ambiguity has historically been tied to particular sentential operators that have been the focus of philosophical scrutiny because of their close connections with topics central to logic, metaphysics, and epistemology.

The semantic treatment of sentences such as ‘Juan believes that Dimitri’s plane is late’ has been mired in controversy for over 100 years, because of the assumption that the semantics of belief sentences cannot be worked out until a theory of belief is developed. For example, some have argued that *de re* readings of ‘believes that’ sentences do not even make metaphysical sense, on the grounds that there is no direct belief about individuals, but only belief about those individuals under some manner of representing them (Kaplan, 1968). Likewise, the correct semantic treatment of sentences, such as ‘It is possible that Dimitri’s plane is late,’ has been thought to depend on who, among logicians and metaphysicians, has the correct theory of modality (i.e., of necessity and possibility). In fact, some philosophers have argued that *de re* readings of modal sentences do not make metaphysical

sense, because they rely on a purportedly dubious distinction between ‘necessary’ and ‘merely contingent’ properties of objects (Quine, 1956). It is essential therefore, when encountering discussions of the *de re/de dicto* distinction, to be clear on whether the discussion is about syntactic representation, semantic interpretation, or metaphysical import.

Default Semantics

K Jaszczolt, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

It is hardly contestable that the interpretation of the speaker's utterance by the addressee is frequently driven by the salience of some of the possible interpretations. This salience can be caused by a greater frequency of a certain meaning or by its simplicity, but ultimately it rests on knowledge of social and cultural conventions or the cognitive principles that govern our thinking. Default Semantics concerns such cognitive defaults.

Before laying out the principles of Default Semantics, it is necessary to situate the default-based views in the research on the semantics/pragmatics interface. According to the traditional view, in addition to lexical and syntactic ambiguities, there are also semantic ambiguities such as that between the wide and narrow scope of negation in (1), represented in (1a) and (1b) respectively. 'KoF' stands for 'present king of France'.

- (1) The present king of France is not bald.
- (1a) $\neg \exists x (\text{KoF}(x) \ \& \ \forall y (\text{KoF}(y) \supset y = x) \ \& \ \text{Bald}(x))$
- (1b) $\exists x (\text{KoF}(x) \ \& \ \forall y (\text{KoF}(y) \supset y = x) \ \& \ \neg \text{Bald}(x))$

The ambiguity position, held by Russell, among others, has been successfully refuted. Instead, it has been proposed that such differences in meaning belong to what is implicated rather than what is said (Grice, 1975), and subsequently that semantics can be underspecified as to some aspects of meaning and require pragmatic intrusion in order to arrive at the full propositional representation of the utterance (see, e.g., Carston, 1988, 2002). It is now usual to talk about the *underdetermination* of sense and *underspecification* of the logical form. According to some post-Griceans, such differences in meaning can be explained through default interpretations. The level of defaults has been conceived of in a variety of ways: as belonging (i) to semantics (as in Discourse Representation Theory, Kamp and Reyle, 1993, and its offshoots, such as Segmented Discourse Representation Theory, Asher and Lascarides, 2003) (*see Discourse Representation Theory*); (ii) to pragmatics (Bach, 1994); or (iii) to fully fledged social and cultural conventions, called presumptive meanings or generalized conversational implicatures (Levinson, 2000). All of these default-based approaches advocate some degree of semantic underdetermination, understood as conceptual gaps in the output of lexicon and grammar. In other words, the logical form,

which is the output of the grammatical processing of a sentence, does not provide the totality of meaning of the proposition expressed by the speaker.

While this statement is certainly true, and while it also seems to be true that some pragmatic contribution is often required in order to get the correct truth conditions of the utterance, it does not mean that such an underspecified or underdetermined representation need be distinguished as an epistemologically real level in utterance processing. In Default Semantics, there is no semantic ambiguity, but there is no underspecification either. The logical form as the output of syntactic processing interacts with the information coming from the property of mental states of *having an object*, *being about* something, called their *intentionality*. So, if we ask where meaning comes from, we can point to two sources of meaning: (i) compositionality of the sentence meaning and (ii) intentionality of the mental state that underlies the sentence. Both are equally basic and equally important, and hence it would be incorrect to consider any information coming from intentionality as an additional, pragmatic level of utterance processing. They both belong to semantics. In dynamic approaches to meaning, such as Discourse Representation Theory, such a level of representation, called in Default Semantics an *intentionality-compositionality merger*, has been successfully implemented and seems to be more in the spirit of dynamic meaning than postulating any unnecessary underspecifications or ambiguities (see Jaszczolt, 1999a, 1999b, 2000).

Default Semantics is governed by three main principles: the Parsimony of Levels (PoL), Degrees of Intentions (DI), and the Primary Intention (PI):

- PoL: Levels of senses are not to be multiplied beyond necessity.
- DI: Intentions in communication come in various degrees: they can be stronger or weaker.
- PI: The primary role of intention in communication is to secure the referent of the speaker's utterance.

In PoL, the principle of parsimony with respect to the proposed levels of meaning is taken further than in other post-Gricean approaches. Instead of discerning an underspecified logical form and pragmatic intrusion, both sources of meaning are treated on an equal footing and both contribute to a common level of representation (the intentionality-compositionality merger). DI and PI principles specify how intentionality contributes to the meaning representation. In agreement with the phenomenological tradition (Husserl, 1900–1901), we have defined intentionality as the property of beliefs, thoughts, doubts, etc.,

of being about an object. It is compatible with the definition of intentionality that this aboutness can be stronger or weaker. For example, a definite description 'the best Italian painter' can correspond to a thought about a particular individual, e.g., Michelangelo (and be used *referentially*); to a thought about a particular individual who does not correctly match the description, e.g., Picasso (i.e., there is a referential mistake); or finally to a thought about whoever happens to undergo the description (and be used *descriptively*). In the first case, intentionality is in the strongest form: as a property of the mental state, it reaches, so to speak, a real object. In the middle case, it is weaker: a real object is intended, but there is no such object corresponding to that description, and hence it reaches a mental construct that is a composite of the real person and an incorrect description. In the final case, the intentionality is dispersed and does not reach an object.

Now, intentional mental states need vehicles of meaning, and language is one such vehicle. As a result, linguistic expressions share the property of intentionality, and hence we can talk about intentionality of utterances as well as intentionality of thoughts. On the level of utterances, this intending is realized as *intentions in communication*. Three types of such intentions are distinguished in Default Semantics: an intention to communicate certain content, to inform about certain content, and to refer to objects, states, events, and processes. In accordance with the DI and PI principles, information from the degree of intentionality of the mental state (or the strength of intending, informativeness of an utterance) merges with the information from compositionality and produces the complete propositional representation that conforms to PoL. So, Default Semantics offers a more economical alternative to the approaches founded on underspecified semantics in that it implements Occam's razor (the methodological principle of not multiplying beings beyond necessity) 'one level up.' Semantic representation structures of Discourse Representation Theory have been implemented as formalizations for such intentionality-compositionality mergers (Jaszczolt, 1999b, 2000, in press a).

The DI and PI principles, in recognizing degrees and strengths of intentions, explain how default interpretations can arise. In the case of definite descriptions such as 'the best Italian painter,' the hearer normally assumes that the speaker utters the description with a referential intention and that the description is used correctly. This assumption is further corroborated by the assumed intentionality of the speaker's belief: the intentionality is strongest when a particular, identifiable individual has been intended.

By force of the properties of vehicles of thought discussed in this article, the stronger the intentionality, the stronger the speaker's intentions. In the case of definite descriptions, the stronger the intentionality, the stronger the referential intention. In the case of definite descriptions, there are three degrees of intentionality corresponding to the three readings distinguished previously: (i) the strongest, referential; (ii) the intermediate, referential with a referential mistake; and (iii) the weakest, attributive. The strongest intentionality corresponds to the default reading. This default reading arises instantly, as a compositionality-intentionality merger. Only if addressees have evidence from their knowledge base or from the context that this default is not the case does the default interpretation *fail to arise*. This procedure is an improvement on other default-based approaches where defaults have to be *canceled* or *overridden*. Cancellation of defaults is a costly process and should not be postulated lightly: if there is no evidence of such cancellation, it is better to do without it and assume a more economical model of utterance processing.

Similarly, cognitive defaults can be discerned for belief and other propositional attitude reports. Sentence (2a) can give rise to a report, as in (2b).

- (2a) The best Italian painter painted this picture.
 (2b) Mary believes that the best Italian painter painted this picture.

Using the representation of the Discourse Representation Theory (Kamp and Reyle, 1993; Reyle, 1993), we can represent the possible readings of (2) as in Figure 1 (Jaszczolt, 1999b: 287):

The discourse referent y is enclosed by a box drawn with a broken line, which signals that y can belong to any of the three remaining boxes. If it belongs to the outermost box, the reading is *de re* (about a particular individual, say, Michelangelo). Placed in the middle box, it signals that Mary has a *de re* belief

Figure 1 A combined DRS for the three readings of (2b).

but is referentially mistaken, thinking, for example, of Picasso. Placing *y* in the innermost box corresponds to a belief about whoever undergoes the description, i.e., a belief in a proposition (*de dicto*) rather than about a particular individual. Analogously to the case of definite descriptions where referential use was the default, the *de re* reading of a belief report comes out as a default, because it corresponds to the strongest intentions and the strongest intentionality. So, Figure 1 comprises three possible representations (three possible compositionality-intentionality mergers).

In addition to definite descriptions in extensional and in propositional attitude contexts, the mechanism of the principles of Default Semantics has been applied to a variety of language expressions and constructions, including proper names (Jaszczolt, 1999b), presuppositional expressions (Jaszczolt, 2002a, 2002b), expressions of temporality and modality, and tentatively to numerals and sentential connectives (Jaszczolt, in press b, in press c). Naturally, the PI principle will not always be relevant. The referential intention will not always be present, and even when it is, it may not pertain to the assessment of the default or nondefault status of various readings. For example, in an assessment of the default meaning of *will* from among the epistemic necessity *will* in (3), dispositional necessity *will* in (4), and a marker of future tense in (5), it is the intention to inform the addressee about a certain content that is graded from the strongest to the weakest:

- (3) Mary will be in the opera now.
- (4) Mary will sometimes go to the opera in her tracksuit.
- (5) Mary will go to the opera tomorrow night.

The Default-Semantic account of *will* also demonstrates that modal and temporal senses of *will* are traceable to one, overarching modal concept (akin to the sentential operator of *acceptability* in Grice, 2001). And since *will* is modal, it follows that the assignment of defaults has to be reversed as compared with the examples previously discussed: the weakest intentionality corresponds to the default sense of *will*, and this, predictably, turns out to be the regular future marker in (5) (for a formal account, see Jaszczolt, in press a).

Not all default interpretations are reducible to cognitive defaults. For example, the interpretation of possessives, as in (6), is dependent on the addressee's background knowledge and the context, rather than on the properties of mental states.

- (6) Peter's book is about a glass church.

Similarly, inferences to a stereotype ('female nurse'), such as in (7), are not the case of the strength of intending but rather stem from the acquaintance with social and cultural practices.

- (7) They employed a nurse to look after the patient.

Such default interpretations belong to the category of social and cultural defaults and are not always of central interest to semantic theory.

The phenomenon of negative-raising, i.e., the tendency for negation on the main clause to be interpreted as negation on the subordinate clause, is not an obvious cognitive default, but here we must be cautious. Neg-raising unpredictably applies to some relevant verbs but not to others, as (8) and (9) demonstrate.

- (8) I don't think he is dishonest. (communicates, defeasibly: 'I think he is not dishonest.')
- (9) I don't hope he will win. (does not communicate: 'I hope he will not win.')

The important question at this point is to ask about the scope of applicability of the theory. The question of the scope of applicability can be taken in the narrow and in the wide sense. In the narrow sense, we ask which default interpretations can be regarded as cognitive defaults, traceable to the properties of mental states. Cognitive defaults are rather widespread. In addition to the examples already mentioned, numerals seem to default to the 'exactly' meaning, rather than being underdeterminate between 'at least,' 'at most,' and 'exactly,' or having an 'at least' semantics. The enrichment of some sentential connectives such as *if* (to 'if and only if') and *or* (to exclusive *or*) can possibly also be traced to the strength of the informative intention and intentionality. This proposal concerning connectives and numerals is still highly programmatic and in need of further research. It is signaled here in order to shed some light on possible applications of cognitive defaults. In the wide sense, Default Semantics also comprises social and cultural defaults simply by assigning them an epistemological status that has nothing to do with the compositionality-intentionality merger.

To sum up: Default Semantics postulates a level of utterance interpretation called a compositionality-intentionality merger and thereby significantly decreases the role of underspecification in semantic theory. It distinguishes cognitive defaults and intention-based degrees of departures from these defaults, triggered by the addressee's knowledge base and the context. The theory also acknowledges the existence of social and cultural defaults whose source lies beyond semantics proper.

Definite and Indefinite

B Abbott, Michigan State University, East Lansing, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

What Does 'Definite' Mean?

'Definite' and 'indefinite' are terms that are usually applied to noun phrases (NPs). In English, *the* is referred to as 'the definite article,' and *a/an* as 'the indefinite article.' Noun phrases (NPs) that begin with *the* (e.g., *the Queen of England, the book*), which are also called (especially in the philosophical literature) 'definite descriptions,' are generally taken to be prototypical examples of definite NPs in English. However, it should be noted that not all of them show the same pieces of behavior that have come to be taken as criterial for definiteness. Similarly, NPs that begin with *a/an*

(*an elephant, a big lie*), 'indefinite descriptions,' are prototypical examples of indefinite NPs. (Plural indefinite descriptions use the determiner *some*.)

Uniqueness?

Exactly what differentiates definite from indefinite NPs has been a matter of some dispute. One tradition comes from the philosophical literature, more specifically Bertrand Russell's classic work on denoting phrases (Russell, 1905). On this tradition, what distinguishes *the* from *a/an* is uniqueness – more specifically the existence of one and only one entity meeting the descriptive content of the NP. So, while use of an indefinite description in a simple, positive sentence merely asserts existence of an entity meeting the description, use of a definite description asserts in addition its uniqueness in that regard. While (1a), on this

view, is paraphrasable as (1b), (2a) is equivalent to (2b).

- (1a) I met an owner of El Azteco.
- (1b) There is at least one owner of El Azteco whom I met.
- (2a) I met the owner of El Azteco.
- (2b) There is one and only one owner of El Azteco, and I met that individual.

It should be noted that Russell was concerned to capture the meaning of definite descriptions in a formal language of logic. Also, on his analysis both definite and indefinite descriptions are quantificational expressions (like explicitly quantified NPs, such as *every apple*, *no unwanted visitors*). The idea that definite descriptions are quantificational has been questioned by others, who view these NPs instead as referential. Fewer people question the idea that indefinite descriptions are quantificational, although some (primarily linguists, rather than philosophers) assume that they, too, are referential.

The uniqueness theory seems to accord well with our intuitions. It also is supported by the fact that when we stress the definite article contrastively, it brings out the sense of uniqueness. Example (3) seems to be inquiring as to whether there is more than one owner, or only one.

- (3) Did you meet an owner of El Azteco or the owner?

It might seem that this approach would necessarily be confined to singular NPs. However, as argued by Hawkins (1978), the notion of uniqueness can be extended to plurals by employing the idea of exhaustiveness – the denotation of a definite consists of everything meeting the descriptive content of the NP. An NP like *the owners of El Azteco* would thus be held to be very similar to *all the owners of El Azteco*.

The first challenge to Russell's analysis of definite descriptions was put forward by P. F. Strawson, who argued that sentences containing definite descriptions are not used to assert the existence and uniqueness of an entity meeting the descriptive content in question. Instead, Strawson argued, definite descriptions are referential NPs, and the existence and uniqueness of a referent is presupposed (cf. Strawson, 1950; in this seminal work, Strawson did not use the term 'presuppose,' although it appeared very quickly in reference to the phenomenon in question). Strawson also argued that if the presupposition fails, the sentence as a whole is neither true nor false. Thus, in the case of (2a), should it turn out that no one owns El Azteco (perhaps it is a government installation), an addressee of (2a) would not respond "That's false!" but would correct the speaker's mistaken presupposition.

Another, more serious problem for Russell's analysis has attracted a lot of attention more recently, and that is the fact that in a great number of cases, perhaps the vast majority, the descriptive content of a definite description is not sufficient to pick out a unique referent from the world at large. One example of such an 'incomplete description' is in (4).

- (4) Please put this on the table.

The sentence in (4) is readily understandable despite the fact that the world contains millions of tables. There are two main kinds of approach to dealing with this problem. A syntactic solution would propose that there is sufficient additional descriptive material tacitly present in the NP – e.g., *the table next to the armchair in the living room of the house at 76 Maple Avenue, Eastwood, Kansas, USA*. But it would be hard to explain how an addressee would guess which descriptive content had been left tacit. On a more plausible approach, the uniqueness encoded in definite descriptions should be understood relative to a context of utterance, which would include only those items in the surroundings of the discourse participants and those items mentioned in the course of the conversation or understood to be relevant to its topic. However, this runs into a problem with examples like (5), first pointed out by James McCawley (McCawley, 1979).

- (5) The dog got into a fight with another dog.

David Lewis proposed that definite descriptions denote the most salient entity meeting the descriptive content (Lewis, 1979).

Familiarity?

The other main tradition concerning the meaning of definiteness generally cites the Danish grammarian Paul Christophersen. In Christophersen's view, what distinguishes definite from indefinite descriptions is whether or not the addressee of the utterance is presumed to be acquainted with the referent of the NP. In an often cited passage, Christophersen remarked: "Now the speaker must always be supposed to know which individual he is thinking of; the interesting thing is that the *the*-form supposes that the hearer knows it too" (Christophersen, 1939: 28). This approach appears to fare better with examples like (4), where, indeed, it seems that the speaker must be assuming that the addressee knows which table the speaker is referring to.

Within current linguistic theory, the familiarity approach was revived by the work of Irene Heim (1982, 1983). Like Strawson, Heim argued that definite descriptions are referential rather than quantificational; however, she also argued that indefinite

descriptions are referential as well. Heim took the uses of definite and indefinite descriptions as they occur in (6) as typifying their semantics.

- (6) Mary saw a movie last week. The movie was not very interesting.

In the mini discourse in (6), the indefinite NP *a movie* is used to introduce a new entity into the discourse context. Subsequently that entity is referred to with a definite (*the movie*). Notice that we might as easily have referred to the movie in the second sentence of (6) with a pronoun: ...*It was not very interesting*. Heim grouped pronouns and definite descriptions together as being governed by a “Familiarity” condition: use of a definite is permitted only when the existence of the referred-to entity has been established in the particular discourse. Indefinite descriptions, on the other hand, are subject to a “Novelty” condition: they presuppose that their referent is being introduced into the discourse for the first time. It’s easy to see that this will solve the problem of incomplete descriptions. An example like (5) would be used only when the first dog referred to was presumed to be known to the addressee.

Though the familiarity theory is very plausible for a number of uses of definite descriptions, there are some kinds of cases it does not appear to cover very well. One of these is definite descriptions where the descriptive content of the NP is sufficient to determine a unique referent, no matter what the context. Some examples are given in (7).

- (7a) Mary asked the oldest student in the class to explain everything.
(7b) Philip rejected the idea that languages are strictly finite.

Here we need not assume that the addressee is familiar with the referents of the underlined NPs or that these referents had been mentioned previously in the conversation. Note, too, that in this kind of case, the indefinite article is not allowed, as shown in (8). (The asterisk in front of these examples indicates that they are not well formed.)

- (8a) * Mary asked an oldest student in the class to explain everything.
(8b) * Philip rejected an idea that languages are strictly finite.

And even when the descriptive content is not sufficient to determine a unique referent relative to the whole world, there are examples where the content may determine a unique referent in context. In these cases, too, the definite article may be used, even if the addressee is not assumed to know who or what is being talked about. An example is given in (9).

- (9) Sue is mad because the realtor who sold her house overcharged his fee.

Adherents to the familiarity theory often invoke the idea of accommodation (following Lewis, 1979) to explain these uses. The idea is that addressees are willing to accept a definite description if they are able to figure out the intended referent.

Some Puzzling Cases

While most occurrences of definite descriptions are consistent with both the uniqueness theory and the familiarity theory, there are several kinds that don’t match either theory. One group of examples is given in (10).

- (10a) Horace took the bus to Phoenix.
(10b) The elevator will take you to the top floor.

It seems that with modes of transportation, a singular definite description can be used despite the fact that there are, e.g., many buses to Phoenix, and the building in (10b) may have many elevators. We also don’t suppose that the addressee will be familiar with the particular bus or elevator in question. A different kind of case is illustrated in (11).

- (11a) My uncle wrote something on the wall.
(11b) We camped by the side of a river.
(11c) She shot herself in the foot.

These sentences are well formed even though rooms typically have more than one wall, rivers more than one side, and people more than one foot. It may be relevant that these are locations. In all of these cases, as pointed out by Du Bois (1980), to use an indefinite article puts too much emphasis on the location, as though it were inappropriately being brought into focus.

A third kind of example shows some dialectal variation. The example in (12) is well formed in American English, although in British English the article would be missing from the underlined NP.

- (12) My mother is in the hospital.

Compare the examples in (13), which are good in both dialects.

- (13a) Bill went to school this morning.
(13b) If you’re very good, you’ll get to heaven some day.

The examples in (14), also good for English in general, indicate a certain amount of idiomaticity.

- (14a) I heard it on the radio.
(14b) I saw it on TV.

It seems that some nouns simply require the definite article, while others are fine without it.

Finally, some adjectives call for the definite article in English, despite their not restricting the reference of NPs they occur in to either a unique or a familiar referent.

- (15) She gave the wrong answer and had to be disqualified.

It is not clear whether these examples indicate the need for a brand-new theory of the definite article in English or are just idiomatic exceptions to the rule.

Grammatical Phenomena

Sensitivity to definiteness of NP is called a definiteness effect, and a number of constructions are believed to have such an effect.

Existential Sentences

One of the earliest constructions showing a definiteness effect to be noticed was existential, or *there be*, sentences. Examples like those in (16) are quite natural, but the corresponding sentences in (17) sound peculiar, if not downright ungrammatical.

- (16a) There is a book in the shop window.
 (16b) There were some bachelors on board the ship.
 (17a) * There is the book in the shop window.
 (17b) * There were the bachelors on board the ship.

One complicating factor is the existence of a construction that is similar to the existential construction but that is used in a restricted set of circumstances. The latter kind of sentence, often called a list existential, typically seems to be used to offer entities to fulfill some role or purpose. However, this kind of existential does not allow a locative prepositional phrase to follow the focus NP. Examples just like those in (17) but where the prepositional phrase is an NP modifier, as in (17'), could be used in reply to the questions in (18).

- (17'a) There is the book in the shop window.
 (17'b) There were the bachelors on board the ship.
 (18a) What can we get for Bill for his birthday?
 (18b) Weren't there any people around to help?

The more common type of existential, like those in (16), can be called locative existentials. In this case, the prepositional phrase that follows the focus NP is a separate constituent that locates the item in question. It is only locative conditionals that show a definiteness effect, and these have been used as a test for definiteness, as we see in the section 'Other Kinds of Definite and Indefinite NPs.'

The *Have* Construction

Another construction, similar to existential sentences, is one involving the verb *have* when it is used to indicate inalienable possession. Here, too, we see a definiteness effect, in that the examples in (19) are natural, while those in (20) are not.

- (19a) She had a full head of hair.
 (19b) He had a sister and two brothers.
 (20a) * She had the full head of hair.
 (20b) * He had the sister and the two brothers.

It is perhaps not too surprising that these two constructions should show a similar definiteness effect, since *have* and *be* verbs are often used for similar kinds of propositions in the world's languages.

Other Kinds of Definite and Indefinite NPs

As shown in the first section, there is no commonly agreed on essence of definiteness or indefiniteness. Hence the need for some kind of diagnostic for these properties. Ability to occur naturally in a locative existential has become the main diagnostic used.

Other Kinds of Definite NPs

As noted in this article, Heim assumed that pronouns are definite, like definite descriptions. Others agree with this categorization. And as we might expect, pronouns do not go naturally in locative existentials. The sentences in (21) are not natural.

- (21a) * There was it in the fireplace.
 (21b) * There were them all over the floor.

Pronouns seem to fit both the uniqueness and the familiarity conceptions of definiteness. When they are used, it is assumed that there is a unique intended referent within the discourse context, and it is also assumed that the addressee will know who or what the speaker was intending to refer to.

Another subcategory of NP that is typically assumed to be definite consists of proper names. Like pronouns and definite descriptions, these do not occur naturally in locative existentials.

- (22a) * There was Joan in the library.
 (22b) * There is France in the United Nations.

Although it might not be so obvious as it is with pronouns, proper names also seem definite by both theories of definiteness. Proper names behave as though they have a unique referent; they cannot accept restrictive adjectives or other restrictive modifiers. And in fact in most contexts, each proper name does have a unique referent. On the other hand, we do not usually use a proper name unless we assume that our addressee has already been introduced to the referent.

A third kind of NP that is generally agreed to be definite would be those that have a demonstrative determiner: *this*, *that*, *these*, or *those*. These cannot occur naturally in a locative existential, as shown (23) and (24).

- (23a) * There was that book over there in Mary's bag last Tuesday.
 (23b) * There are these applicants waiting to see the dean.

In addition, NPs with a possessive determiner are usually classed as definite.

- (24) * There was Mary's car in the driveway.

Indeed, NPs with possessive determiners are typically regarded as belonging to the category of definite descriptions.

Some kinds of quantified NPs cannot occur naturally in existential sentences, and this has led some people to consider them to be definite NPs. Some examples are given in (25).

- (25a) * There were all the students at the party.
 (25b) * There were most red buttons on the dress.

However, it is possible that these NPs should not be classified as definite and that there is some other reason that they cannot occur in locative existential sentences.

Bare NPs

One interesting kind of NP in English has received a significant amount of attention. So-called bare NPs do not have any determiner, and the head noun must be either plural or a mass noun. These NPs have (at least) two distinct uses. Sometimes they are interpreted generically, as in (26).

- (26a) Mary likes sharpened pencils.
 (26b) Water with fluoride in it is good for the teeth.

The sentences in (26) concern the whole category referred to by the underlined NP. On the other hand, sometimes these bare NPs have an existential interpretation, in that they are referring to just some members or a subpart of the category.

- (27a) Mary bought sharpened pencils.
 (27b) There was water with fluoride in it in the test tube.

As can be seen in (27b), when bare NPs occur in a locative existential sentence, they can have only the existential interpretation, and not the generic one.

Other Types of Indefinite NPs

In addition to indefinite descriptions, and bare NPs with the existential interpretation, there are other

types of NPs that go naturally in locative existentials. Some examples of quantified NPs are shown in (28).

- (28a) There are a few pieces of cake left.
 (28b) There were few, if any, freshpersons at the school fair.
 (28c) There are many problems for that course of action.
 (28d) There are some big flecks of paint on the back of your coat.

If we use natural occurrence in a locative existential as a diagnostic, then these other types would also be classified as indefinite NPs.

In addition to these, there are some other unexpected cases of NPs that look as though they should be definite, because they have definite determiners, but that can appear naturally in a locative existential. One kind, noticed first by Prince (1981), uses the proximal demonstrative determiner (*this*, *these*), but with an indefinite reference, as in (29).

- (29a) There was this strange note on the blackboard.
 (29b) There are these disgusting globs of stuff in the bowl.

Note that this is definitely a different use of these determiners. The examples in (29) would not be used with any kind of pointing gesture, and indeed, they could be used in a phone conversation, where the addressee is not in the same perceptual situation as the speaker. Also, it is worth noting that this indefinite use of *this* and *these* is somewhat marked stylistically. Examples like those in (29) would not appear in a formal context.

Finally, there are some kinds of NPs that look like definite descriptions, but whose sense is indefinite, and that can appear naturally in existentials.

- (30a) There was the nicest young man at the picnic!
 (30b) There were the same nominees on both ballots.

As Prince (1992) pointed out, an NP like *the same nominees* can have two interpretations. One is anaphoric, as in (31).

- (31) The Executive Committee came up with a list of nominees, and it happened that the Nominating Committee chose the same nominees.

Here *the same nominees* refers back to the Executive Committee's list and means that the Nominating Committee's choices were the same as the Executive Committee's. On this interpretation, *the same nominees* would be definite. However, the interpretation in (30b) is different: it means that the two ballots had the same choices. This interpretation is apparently indefinite, given the ability of this NP to occur naturally in the existential sentence in (30b).

Other Kinds of Categorizations

A simple binary distinction like definite vs. indefinite may be too crude, especially if we are trying to classify NPs in general. Furthermore, it may be more useful to look at the role of NP form with respect to discourse function. A number of researchers have turned to the idea of information status – an extension of the familiarity idea, but with greater articulation.

Old and New

Prince (1992) argued that we need to distinguish two ways in which information can be novel or familiar, new or old. One is with respect to (the speaker's assumption about) the addressee, which Prince called Hearer-old and Hearer-new. The speaker assumes that the addressee is already acquainted with the referent of a Hearer-old NP, whereas Hearer-new NPs are assumed to introduce new entities to the addressee. On the other hand, entities can be new or old with respect to a discourse: Discourse-old or Discourse-new. Discourse-old NPs refer to entities that have already been mentioned in the current discourse, in contrast to Discourse-new NPs. Prince found that it was the category of Hearer-old/Hearer-new that correlated roughly with the definite/indefinite distinction, rather than Discourse-old/Discourse-new. This seems to agree more with Christophersen's than with Heim's conception of definiteness and indefiniteness.

The Givenness Hierarchy

Gundel *et al.* (1993) proposed a hierarchy of givenness corresponding to the degree to which the referent of an NP is assumed to be cognitively salient to the addressee. Each point in the hierarchy corresponds to one or more NP forms. At one end of the hierarchy is the weakest degree of knownness, which Gundel *et al.* labeled 'type identifiable.' This end corresponds to indefinite descriptions, and the criterion for their use is just that the addressee be familiar with the kind of thing denoted. At the other extreme, we find NPs denoting entities that are currently 'in focus,' and pronouns require this extreme of cognitive salience.

Definite descriptions are about midway in the hierarchy, requiring unique identifiability for their referents. Just to the weaker side are the indefinite *this/these* NPs. On the more salient side of definite descriptions are NPs with demonstratives (*this, that, these, those*) as determiners.

One special aspect of this treatment is that the criteria for each place on the hierarchy are increasingly stringent and subsume the criteria for all less stringent points; that is, the hierarchy is an implicational

one. Hence, indefinite descriptions, which have the weakest requirement, can appear anywhere in principle – even when their referents are in focus. However, general conversational principles militate against using an indefinite description in such a situation, as it would be misleading in suggesting that only the weakest criterion had been satisfied.

The Accessibility Hierarchy

A third approach, similar to the one just mentioned but with its own distinct characteristics, was developed by Mira Ariel (1990, 2001). Ariel proposed an even more articulated accessibility hierarchy, reflecting the marking of NPs according to how accessible in human memory their referents should be. Upwards of 15 distinct categories are represented, ranging from full name plus modifier (at the least accessible end) to zero pronouns (represented with \emptyset), which are found in constructions like those in (32).

- (32a) Mary wanted \emptyset to build a cabin.
 (32b) Open \emptyset in case of fire.

Full name plus modifier (e.g., *Senator Hillary Clinton*) is distinguished from full name, last name alone, or first name alone, each of which receives a separate spot on the hierarchy. Similarly long definite descriptions, with a lot of descriptive content, are distinguished from short ones, and stressed pronouns from unstressed pronouns. (The list does not contain quantified and [other] indefinite NPs, which, as noted in this article, are often considered not to be referential expressions.)

Ariel's claim was that the hierarchy of NP forms corresponds to accessibility, where the latter is determined by a number of factors, including topic-hood, recency and number of previous mentions, and how stereotypic the referent is for the context. The NP forms go generally from fullest and most informative to briefest and least informative, \emptyset being the limiting case. The idea is that an NP form typically encodes an appropriate amount of information for the addressee to achieve easy identification of the referent.

Definite and Indefinite in Other Languages

The examples used so far in this article have been taken from English. However, many other languages have definite and/or indefinite articles, though by no means all of them. Lyons (1999) described the explicit marking of definiteness – whether with an article or a nominal inflection – as an areal feature that characterizes the languages of Europe and

the Middle East in particular, although it can be found elsewhere in the world as well (Lyons, 1999: 48). Definite articles often seem to develop out of demonstrative determiners, as was the case in English. Indefinite articles, on the other hand, often come from the word for 'one.'

Some languages, e.g., Irish (Irish Gaelic), have only a definite article, whereas others, e.g., Turkish, mark only indefinites explicitly. The examples in (33) and (34) are taken from Lyons (1999: 52).

- (33) *Irish*
 (33a) an bord 'the table'
 (33b) bord 'a table'
- (34) *Turkish*
 (34a) ev 'house', 'the house'
 (34b) bir ev 'a house'

Even among languages that have both definite and indefinite marking, the usages typically do not match exactly across languages. Thus, bare NPs in English have a generic use (as in the examples in [26]). French also has both definite and indefinite determiners but, unlike English, would use the definite determiner in examples like those in (26).

- (35) *French*
 (35a) Marie aime les crayons bien taillés.
 (35b) L'eau au fluor est bonne pour les dents.

In languages that do not use articles or some other explicit marking for definiteness or indefiniteness, word order may affect interpretation in that way, as in the examples in (36) and (37), from Chinese and Russian.

- (36) *Mandarin Chinese*
 (36a) Zhuo-zi shang you shu.
 table on have book
 'There is a book (or books) on the table.'
 (36b) Shu zai zhuo-zi shang.
 book is located table on
 'The book is on the table.'
- (37) *Russian*
 (37a) Na stolé lezhít karta.
 on table lies map
 'There is a map lying on the table.'
 (37b) Karta lezhít na stolé.
 map lies on table
 'The map is lying on the table.'

However, it should be noted that word order variation also interacts with topicality and the distribution of new and old information in a sentence and that this affects the definiteness or indefiniteness of an NP's interpretation.

For a full discussion of the expression of definiteness and indefiniteness in a variety of the world's languages, see Lyons (1999).

Definitions: Uses and Varieties of

G Longworth, Birkbeck College, University of London, London, England, UK

© 2006 Elsevier Ltd. All rights reserved.

Uses

'Definition' is the activity of explaining to an audience the meaning of an expression. 'A definition' is a product of that activity: a sentence the understanding of parts of which (the part of the sentence providing explanation, the *definiens*) can underwrite an audience's understanding of the rest (the part of the sentence being defined, the *definiendum*). For example, understanding 'is the activity of explaining the meaning of an expression' (*definiens*) might enable one to understand a meaning of 'definition' (*definiendum*). Notice that 'definition' needn't proceed via 'definitions.' Perhaps the first explanations of meaning to which a child is exposed don't come via sentences.

Besides the immediate purpose of underwriting explanations of meaning, a definition can serve countless others. One may stipulate that an expression is to enjoy a meaning – deploying a 'stipulative definition.' E.g., for purposes of this entry, let *x* be a *definition* if *x* is a sentence used to explain meaning. (Here and throughout, initial universal quantification is suppressed and use/mention distinctions ignored.) Other purposes of stipulation include abbreviation – hence, 'abbreviative definition' – itself at the service of tractability and comprehensibility – and marking out the *definiens* as of special interest, perhaps as carving at an important joint (Whitehead and Russell, 1910).

An alternative purpose is to describe the meaning an expression carries with respect to some language or population – a 'descriptive' or 'lexical definition.' Thus, in English, *x* is a *definition* iff *x* is a sentence used to explain meaning. Less immediate purposes here include illuminating a less well understood *definiendum* by appeal to a better understood *definiens*;

revealing the basis of one's understanding of the *definiendum*; or establishing dependence of the *definiendum* on the *definiens*. But the basic purpose of descriptive definition – explaining the meaning of the *definiendum* – is independent of the viability of these other purposes. This is good, since it would be surprising if many expressions in use were redundant.

A third purpose is 'explication' or 'explicative definition.' Here one stipulates with the aim of approximating to the meaning of an ordinary expression. The aim is to balance two requirements: first, the new expression should be fit to do duty for the old, at least for some purposes; and second, the new expression should improve upon the ordinary along some valued dimension, perhaps clarity or consistency (Carnap, 1928, 1947). Explication is risky, as it is in general impossible to specify in advance the range of important duties an expression must perform. The definitions recently presented are sufficiently vague and ambiguous to meet the first requirement, if not the second.

Whatever one's purposes, the capacity of a definition to serve them is relative to the context (circumstances) in which the definition is offered. In particular, it is relative to the needs of one's audience and to their capacities and informational situation. The role of audience capacities and collateral information is difficult to articulate in detail, but can be illustrated. Someone who lacks the capacities needed to understand 'explain' will not gain understanding of 'definition' from the definition offered above. Moreover, it's plausible that, since true synonymy (sameness of meaning) is rare, most dictionary definitions rely heavily on audiences' knowledge and abilities, often supplying little more than hints from which the intellectually privileged are able to derive understanding.

Mention of contextual features is often suppressed, especially in logic. Suppression is motivated by aims, such as balancing maximal generality against formal tractability. Aiming for generality induces logicians to

articulate assumptions and rely only on capacities widely possessed amongst thinkers. Seeking tractability induces restrictions on the range of uses of an expression that a definition is required to explain. Logicians typically require definitions to convey meaning to audiences competent with the logical apparatus and language of their logical theory, without relying on special capacities or features of the circumstances in which the definition is offered. It doesn't follow that definitions offered by logicians are more than comparatively context-free. Neither does it follow that explanations of meaning outside of logic are required to attain a similar level of context-freedom.

Varieties

Having seen something of the assortment of uses of definitions, we can consider some varieties of definitions. There are as many forms of definition as there are ways of using sentences to enable someone to discover the meaning of an expression. Those listed below are included for their exhibition of variety, and also because they illustrate the context sensitivity of definition. This is addressed more explicitly in the section 'Uses Again.'

Comparatively Context-Free Forms of Definition

Explicit definition involves assuming an audience to understand the *definiens* in advance, and presenting the *definiendum* as something that can replace the *definiens* for current purposes. For example,

- (1) A **brother** is a male sibling

Here, an audience is informed that *brother* can be used wherever *male sibling* is used. An explicit definition accomplishes this by associating with the *definiendum* an expression that can serve in function-preserving replacements for that expression, perhaps through synonymy, or some weaker equivalence.

An interesting form of quasi-explicit definition is 'recursive' or 'inductive definition.' (Quasi-explicit since it fails to provide an independent expression that can be used wherever the expression to be defined can be used.) A recursive process is one that takes its own outputs as inputs, generating new outputs that can serve as inputs, and so forth. Use of recursive definitions enables us to characterize the meaning – e.g., extension – of expressions when that meaning can, or can only, be generated by a recursive process. For example:

- (2) x is a **direct ancestor** of y iff x is a parent of y or x is a parent of a direct ancestor of y

Here, the *definiendum* appears in the *definiens* so that the extension of the *definiens* cannot be determined in advance of partial determination of the extension of

the *definiendum*. This in turn cannot be determined in advance of partial determination of the extension of the *definiens*. This is apt to seem viciously circular, but it isn't. Vicious circularity is avoided because the basis clause, x is a parent of y , affords a means to start the recursive process independently of grasp of the meaning of x is a direct ancestor of y . The 'inductive step' – or x is a parent of a direct ancestor of y – can then make use of the output of the basis clause to generate a new input, and so forth.

Explicit definition is unhelpful when the framework in which it is given deploys the expression to be defined, or when an audience lacks other expressions able to do the same work. In such cases, one might deploy 'implicit (or contextual) definition.' An implicit definition explains an expression's meaning through appeal to other elements in the definition. But unlike an explicit definition, the other elements in an implicit definition need not be equivalent to the *definiendum*. Implicit definition involves stipulating the truth of sentences involving the *definiendum* in a way that fixes its meaning as the unique meaning able to sustain the truth of the sentences so stipulated.

One example was Bertrand Russell's account of definite descriptions, sentences of the form *The F is G* like *The King of France is bald*. Rather than presenting an explicit definition of *The* or *The F*, Russell explicitly defined whole sentences in which they occur, and thereby implicitly defined them, via (3):

- (3) $\text{The } F \text{ is } G \text{ iff } (\exists x) (Fx \ \& \ (\forall y) (Fy \supset x = y) \ \& \ Gy)$

The right-hand side reads: there is exactly one F and every F is G (Russell, 1905).

Another example involves the use of a definite description to explain a proper name's reference. The reference of *Jack the Ripper* might be explained using the following sentence:

- (4) **Jack the Ripper** is the perpetrator of the Whitechapel murders

Although (4) can be used to explain the meaning of *Jack the Ripper*, it does so without identifying it with the meaning of the descriptive phrase *the perpetrator of the Whitechapel murders*. Proper names – unlike descriptive phrases – are 'rigid designators.' They refer, crudely, to the same object in every possible world. So, while *the perpetrator of the Whitechapel murders* denotes different individuals in different possible worlds – depending on who in those worlds committed the crimes – *Jack the Ripper* refers to the same person in each world: whoever committed the crimes in the actual world. It follows that (4) is only 'contingently' true (might have been false). But, arguably, since (4) is stipulated, it is knowable *a priori* (Kripke, 1980; Evans, 1979; Soames, 2003:

397–422). This effect is mediated by the audience's standing competence with the category of proper names. So this feature of context plays a role in mediating the transition from what is presented in a definition to the understanding conveyed.

Comparatively Context-Dependent Definitions
More obviously context-dependent forms of definition involve appeal to examples, and so to the classificatory abilities of one's audience.

Ordinary explanations of meaning often employ 'ostension' – crudely, pointing. Thus, one may point to Hilary Putnam and utter (5):

(5) **That** is Hilary Putnam

thereby explaining the meaning of *Hilary Putnam*. This is an 'ostensive definition.'

An 'enumerative definition' serves to explain the meaning of an expression by listing at least some elements in the expression's extension. So, for example, (6):

(6) A **Beatle** is Ringo or John or Paul or George

Ostension can be used to facilitate enumeration:

(7) **This** (pointing to Ringo) and **that** (pointing to Paul) are **living Beatles**

Often, enumerative definitions give only partial lists and include an 'and so forth' clause:

(8) A **philosopher** is Hilary Putnam, or W. V. Quine, or Rudolf Carnap, or anything relevantly like those

In (8), since there are indefinitely many ways of continuing the list, we rely on our audience's capacities, in particular the continuations they find salient. In order to reduce reliance, we can give additional information concerning the similarities we expect our audience to track:

(9) A **philosopher** is Hilary Putnam, or W. V. Quine, or Rudolf Carnap, or other things similar to those with respect to academic expertise

An important range of cases involves ostensive enumeration and direction. So, for example,

(10) A sample is **water** iff it is the same liquid as that (pointing to a sample)

According to (10), whether a novel sample counts as water depends on the general requirements on sameness of liquid and on the nature of the original sample. As Hilary Putnam argued, both "... may take an indeterminate amount of scientific investigation to determine" (Putnam, 1975c: 225). Arguably, something close is true of definitions of many ordinary expressions, especially those that employ examples. Development of definitions that are less reliant on context for their functioning than ordinary definitions may require detailed investigation of elements in the circumstances of definition.

Uses Again

The utility of definition depends on how widely it is applicable. There are grounds for pessimism. One negative argument is that, in order for a definition to secure uptake, the *definiens* must be understood. Hence, some basic range of expressions must be understood in advance of any definition, and they will therefore be undefinable. If some expressions can be so understood, it becomes pressing to show that some others cannot. Another negative line is that the role of context in the explanation of meaning establishes that exposure to definitions is, in general, not necessary or sufficient to secure audience understanding. Exposure is insufficient, not only because of the role of context in enabling an audience to utilize a definition to fix on a meaning, but also because elements in the context can play a role in fixing a meaning incompatible with the explicit dictates of the definition. The role of context makes definitions only defeasible guides to meaning. The use of examples above in explaining the varieties of definition makes possible the development – or defeat – of the proffered general characterizations of that variety. Exposure to definitions is unnecessary for a related reason: just as contextual elements can defeat definitions, so they can enable understanding in the absence of definitions.

From the current perspective, these points do not apply to the activity of definition. Since we acquire knowledge of the meanings of many (if not all) of our expressions on the basis of others' explanations – understood to include their uses of expressions in contexts – many expressions with which we are competent are thereby definable. What the points suggest is that meaning can fail to supervene on information acquired just through understanding the *definiens*. (Supervenience of a set of properties *Q* on a set of properties *P* requires that no two possible worlds – or portions of a possible world – can differ in the distribution of *Q*-properties without differing in the distribution of *P*-properties.) But failure of meaning to supervene on the information carried by definitions is perfectly compatible with that information playing a role in sustaining knowledge of meaning. So the two lines of argument canvassed above indicate, at most, that not every ordinary definition will exhibit the degree of freedom from context shown by definitions in logic. The importance of this (potential) result derives from the extent to which philosophers have aimed to offer definitions of key terms – e.g., knowledge, causation, or truth – in a (comparatively) context-free way. One of the major themes of late 20th century philosophy has been that the aim is inappropriate (Burge, 1993; Putnam, 1975a, 1975b, 1975c; Travis, 1989; Wittgenstein, 1953. Related issues arose from Quine's

critique of the view that definitions have distinctive epistemic status: Quine, 1936, 1951, 1963).

Deflationism

G Marti, ICREA & Universitat de Barcelona, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

The label 'deflationary' is applied to different theories of and approaches to philosophical issues nowadays, and there is a bit of confusion as regards what it is that makes a theory deflationist, partly because it is not clear what all so-called deflationary theories have in common. At the risk of oversimplifying, let us say that a philosophical theory of X is deflationary just in case it does not accord to X a fundamental, or underlying, nature amenable to philosophical analysis.

A deflationary theory of X does not deny the existence of X or of things that are X; it doesn't have to deny that either X or the concept of X plays a role in philosophical inquiry about other phenomena; it does not even have to deny that there may be an explanation of why something is X. The important point to remember is that a deflationary explanation does not constitute a philosophical analysis, nor does it presuppose that there is a uniform reason for being X for all things that are X, i.e., a general explanation of what makes something X – for that would presuppose that X has a nature. Here we will focus on two forms of deflationism that are of special interest to the Philosophy of Language: deflationism about truth and about meaning.

Deflationary conceptions of truth have been espoused under different guises by philosophers such as Gottlob Frege, Frank Ramsey, A. J. Ayer, Peter Strawson, and W. V. O. Quine. Main contemporary proponents include Hartry Field and Paul Horwich.

Ramsey (1927) and Ayer (1936) have both stressed in different ways Frege's remark that "nothing is added to the thought by my ascribing to it the property of truth" (1918), p. 88. To say of a sentence *p*, or of the proposition it expresses, that it is true does not add anything to saying *p* itself. In a similar vein, Quine remarked that "by calling the sentence ('Snow is white') true, we call snow white. The truth predicate is a device of disquotation" (1986), p. 12. This does not mean that the predicate 'is true' is useless, nor that it can be eliminated. Indeed, in some sense a deflationist may rest content with the claim that 'is true' expresses a property: contemporary deflationists accept that 'is true' functions grammatically like a predicate, so like every other predicate it can be said to apply a property to a subject. Nevertheless, it makes no sense to think of truth as the property that all true sentences, or true propositions, have in common, for what makes 'Snow is white' true is something having to do with snow and the physical phenomena involved in the reflection and perception of light, whereas what makes 'London is north of Barcelona' true has to do with the cities and their position on the planet; there is no one thing that these two sentences have in common that explains their being both true. This contrasts with the claim that the two sentences have in common their correspondence to facts in the world, as versions of the correspondence theory would have it, and it contrasts also with the claims that the sentences cohere with a system of beliefs or that they both have some sort of pragmatic value, as the coherence and the pragmatic approaches to truth would have. The predicate 'is true' is not eliminable, because it allows us to say things that we could not say without it – for instance, sentences such as 'Everything Tom says is true,' something that can be meaningfully said even when we do not know all the members of the set of things that Tom says. So, 'is true' has a useful application when it is meant to apply to a conjunction of statements not all of whose members are known, or when it is meant to apply to an infinite conjunction of statements. But observe that on such views the function of the predicate 'is true' is purely logical: there is nothing more to the nature of truth than the linguistic function of 'is true.' And as regards the concept of truth, the deflationist proposes that it is completely captured by Tarski's equivalence schema: *p* is true if and only if *p*.

Some contemporary versions of deflationism assume the instances of the schema to be about sentences, so the nature of truth is taken to be entirely

captured by the list of instances: "'Snow is white' is true if and only if snow is white," "'London is north of Barcelona' is true if and only if London is north of Barcelona," . . . This approach, which finds its inspiration in Quine (1986), faces the objection that it makes truth relative to a language. So, what this version of the deflationist project really captures is the notion of 'true-in-English' or 'true-in Spanish,' something that is arguably at odds with the intuitive notion of truth. A different deflationary approach to truth, the minimalist approach championed by Paul Horwich (1990), regards the instances of the T-schema as being about propositions. So the minimalist view is that the nature of truth is entirely captured by instances of the schema: the proposition that *p* is true if and only if *p*. A proposition is what is expressed by an utterance of a sentence in a given context; utterances of, say, 'Snow is white' by an English speaker and of 'La neige est blanche' by a speaker of French express the same proposition. Thus the notion of truth so characterized is not language-relative.

Horwich's minimalist conception of truth has been widely discussed recently. I will not make an attempt here to give a summary of objections and replies. A good state-of-the-art perspective on the discussion can be obtained from Blackburn and Simmons (1999) and an exhaustive presentation of deflationism, its different versions, and the challenges they face can be found in Kirkham (1992). There is, however, a general worry about the deflationist perspective on truth that is worth mentioning. Robust theories of truth such as the correspondence theory take seriously the explanatory relationship between facts, the way things are in some portion of the world, and the truth of sentences that describe those portions of the world. Thus, we assume that snow's being white *explains* why 'snow is white' is true, something that the deflationist also accepts. So, let us then say: "that snow is white explains why 'snow is white' is true," or alternatively "that snow is white explains why the proposition that snow is white is true." The deflationist seems committed to the claim that the latter says nothing over and above "that snow is white explains that snow is white." Perhaps the deflationist may want to answer to this worry by denying that the original intuition, that snow's being white *explains* why 'snow is white' is true, tells the whole story: that it is not snow's being white, but the physical (not philosophical nor semantic) phenomena about the reflection of light and its perception by the human eye that explain why 'show is white' is true.

There is another conception of truth that in a sense does not qualify as deflationary. Yet in another sense it does. This is the approach to truth explored in Cartwright (1987) 'A neglected theory of truth' (an approach for which Cartwright found inspiration

in G. E. Moore), a view according to which truth is a simple, unanalyzable property. True sentences, or propositions, have the property, false ones do not, and that's all that can be said about true and false sentences or propositions. In some sense the view is everything but deflationary, for it accords to truth a nature and a substantial worldly presence. On the other hand, the stance on nonanalyzability goes hand in hand with other deflationary approaches. It is easy to dismiss Cartwright's 'neglected theory of truth' as a non-theory, for it postulates the existence of a property while denying that there is any explanation to be given as regards the conditions for its possession. This sounds akin to claiming that some sentences express necessary truths, while happily declaring that nothing else needs to be said about necessity and contingency. This form of criticism may be blind to an important distinction, one that is important for all forms of deflationism to highlight: it is one thing to reject the need for explanation, and a different thing to deny that there is a **philosophical** explanation of the conditions of possession of a property (or that there is a philosophical explanation of the conditions of application of a concept). Take for instance the concept red and the property of being red. There are lots of things that a physicist can tell us about the conditions for the possession of that property. In this sense, redness is ripe for explanation. Yet, from a philosophical point of view, one may wish to deny that the concept red is amenable to philosophical analysis, and one may regard the property of being red as a basic property that things either have or do not have.

Deflationary accounts of meaning have in common with deflationism about truth the idea that meaning is not some kind of analyzable property that certain signs possess. Use theories of meaning are deflationist, for they postulate that all there is to the meaning of an expression is the use that speakers make of it. Meaning, according to use theories, does not consist in a relation between words and some entity, mental or worldly. As Horwich (1998) put it: "the meaning of a word is constituted from ... the regularities governing our deployment of the sentences in which it appears" (p. 3).

In Horwich's view the meaning of, for instance, 'dog' reduces just to "its use being governed by such-and-such regularity" (p. 6). The appeal to use makes the explanation of the meaning of 'dog' non-semantic. In purely semantic terms all we can say about the meaning of 'dog' is that "dog" means DOG."

As in the theory of truth, there is a conception of meaning, and in particular of the referential link between expressions and the things they name, that is deflationary in the sense that Cartwright's 'neglected

theory' is deflationary. Proponents of Millianism, direct reference theorists, argue that there is no semantic mechanism (descriptive backup or Fregean mode of presentation) connecting a name and its bearer: that reference is direct and unmediated. As was the case with the Moorean theory of truth, it is easy to dismiss this position as a non-theory: if reference cannot be explained or analyzed, if we can say nothing about reference over and above saying that 'Aristotle' refers to Aristotle, it seems that our words refer to pieces of the world by magic. However, what the view really says is that there is no *philosophical* analysis or explanation that will tell us in virtue of what 'Aristotle' refers to Aristotle: the explanation, interesting as it may be, will involve perhaps social, historical, anthropological, physical, and psychological factors.

Deixis and Anaphora: Pragmatic Approaches

K Green, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

'Deixis' is generally understood to be the encoding of the spatiotemporal context and subjective experience of the encoder in an utterance. Terms such as *I*, *here*, *now*, and *this* – the so-called 'pure deictic terms' – are heavily context dependent and represent a kind of cognitive center of orientation for the speaker. What, for instance is *here* for me, may be *there* for you. Clearly such terms pose problems in terms of both reference and meaning, and standard accounts have attempted to find a middle ground between lexical and pragmatic meaning (see Green, 1995). The difference between 'anaphora' and deixis is fairly straightforward again in standard accounts (see Jarvella and Klein, 1982), but an increasing pragmatic emphasis has made the distinction between the two less easy to define. In standard accounts, anaphora is seen as much more of an intralinguistic or intrasentential element. Consider the following sentences:

That man is very tall. He must have trouble buying clothes.

The deictic expression *that man* must be given a pragmatic interpretation, while the pronoun *he* is said to 'refer back' to the foregoing element. But as we shall see, the issue is not so simple.

Anaphora is generally understood to be the process whereby a linguistic element is interpreted derivatively from a foregoing unit – its 'antecedent.' Although it covers a range of expressions that the speaker may use in referring and picking out the intended referent, research has focused almost exclusively on pronominal referring expressions in discourse, for example:

Fred came into the room. He sat down.

The theory of anaphora deals with the relationship between *he*, *Fred*, and the objects that these elements describe or pick out. The most problematic and interesting of anaphoric phenomena are those that are crosssentential or discourse based. In the taxonomy of Hankamer and Sag (1977), the antecedent is not considered to be crucial, and where it is not explicitly stated, the process is known as 'pragmatically controlled anaphora.' However, this is not central to the kind of pragmatic approaches that have recently been explored and indeed is close to what Halliday and Hasan (1986) and Brown and Yule (1983) would call 'exophoric' reference.

Pragmatic approaches to anaphora are part of a larger set of (sometimes conflicting) theories that Breheny (2002) calls 'nondynamic.' Within these

non-dynamic approaches there are two subsections: 'linguistic' and 'pragmatic' approaches, the latter including what has come to be known as (following Cooper, 1979) 'E-type approaches'. A nondynamic linguistic approach to the above example would stipulate that the pronoun in the second sentence is bound to the noun phrase in the first. However, one can still promote a 'linguistic' approach without the idea of crosssentential binding. In this approach, the pronoun serves as a proxy for a definite description and would therefore easily be accommodated within Hankamer and Sag's model. The relationship between antecedent and pronoun is not so much syntactic as paradigmatic; the pronoun deputizes for the noun phrase. Linguistic approaches nevertheless agree that some linguistic rule enables the description to be recovered, whether due to semantic or syntactic considerations (Heim, 1990; Neale, 1990) (*see Semantics–Pragmatics Boundary*).

Pragmatic approaches stress the absence of any generalized linguistic rule that would account for the recovery and interpretation of descriptions in anaphoric contexts. Rather, any principles about the process of recovery must be inferred from more general principles about discourse organization and context. Consider the following example from Breheny (2002):

A man who walked in the park whistled.

Putting aside for the moment whether this is an appropriate sentence for analysis (that is, whether it is pragmatically plausible), two problems are evident here. The first is the problem of uniqueness, a particular difficulty when the antecedent is an indefinite (*a man*). In the model of Evans (1977) there must necessarily be only one man walking in the park; in other words, *a man* cannot be a disguised plural, giving rise to an 'attributive' (after Donnellan, 1978) reading of the phrase *a man who*. What linguistic rule tells us that this is so? The past tense of the verb *whistled* leads us away from any notions of generality as they tend to occur in timeless present contexts (*A man walking in the park whistles*). However, this by no means counts as a linguistic rule and is more readily interpreted through pragmatic means.

Another problem arises with contradictions. Again, consider the following from Breheny (2002):

A: Last night I met a Cabinet minister.
B: She was not a Cabinet minister.

Here, B does not ascribe to the description the property that A thinks it has. The pragmatic approach

would have to rely on the notion of 'implicit content' to interpret this exchange. The proposition expressed by A cannot depend on the actual state of the referent. Clearly, pragmatic approaches can neatly sidestep both the uniqueness and contradiction problems, but they do so at a cost. The way the utterances are interpreted does not seem to rely upon any generalized notions of either discourse organization or contextualization. Rather, there is at most a general assumption about implicit communication, and we have no way of predicting which interpretation is correct or at least the most salient. As Breheny notes, this has led many to look further for some kind of linguistic rule; but there is no reason to suppose that because pragmatic rules are difficult to locate there must be a more formal linguistic answer.

Where a pronoun is apparently bound to an indefinite expression without restriction, certain difficulties arise, as in the following example (the so-called 'donkey anaphora'):

Every farmer who owns a donkey beats it.

The problem for nonpragmatic accounts of anaphora here is that the indefinite (with its *wh*-clause) bound to the pronoun (*every farmer who owns a donkey*) is a quantificational noun phrase that actually has the pronoun in its scope.

Pronouns with definites as antecedents would appear to offer less of a challenge to pragmatic approaches, as in the earlier-cited example of *Fred came into the room. He sat down*. The traditional approach is to regard the pronoun as 'coreferring' to the name *Fred*, thus tying the pronoun variable to the noun phrase constant. But this makes the pronominal reference purely intralinguistic (as an element of 'cohesion') and wholly dependent upon its antecedent. A more pragmatic approach would be to see the pronoun as referring in a different way to that which *Fred* refers to. Just how different and in what way is difficult to specify, but certainly this approach makes pronominal reference of this kind very similar to deictic or exophoric reference; the line between deixis and anaphora is blurred. A problem with the traditional approach, which we might call the 'binding' or 'cohesive' approach, is that in indefinite contexts, what appears to be a straightforward binding of a quantificational expression and a variable (pronoun) does not represent a rule that can be generalized to a meaningful degree. In crosssentential examples such as *I had ten marbles but dropped them. I found nine. It had rolled under the sofa*, because the pronoun is not properly bound to its antecedent, there is no plausible interpretation. However, in the following example from Breheny, *Every boy left school early. He went to the beach*,

the pronoun seems to convert the universal quantifier into an existential one.

There is a considerable body of work devoted to promoting pragmatic approaches to anaphoric interpretations. In general these works share the view that anaphoric reference is interpreted by means of a range of inferential strategies. This is essentially a neo-Gricean approach, as evident in the work, particularly, of Huang (1994), who employs Gricean principles proposed by Levinson (1987).

Much of the debate hinges on the very nature of pronouns and their contexts. Pronouns do not contain what is traditionally thought of as 'descriptive material,' and yet they are used to refer precisely to that material. This has led quite naturally to theories of anaphoric behavior broadly deemed 'substitutional.' Perhaps the most radical attack on these approaches was presented by Jones (1995), who declared the phenomenon of anaphora and its attendant substitution theories a 'hoax.' For Jones, reference is not an intrinsic property of particular language units and therefore not a property that some units have more than others. Broadly pragmatic, Jones's theory sees reference as a contextualized communicative action expressed in and through the properties of an utterance as a whole. Since, for Jones, what is referred to by speakers is outside and beyond the means used to refer to it, there is no possibility of any linguistic constraints on reference. Such a radical view represents the ultimate pragmatic position, but most theorists have been content with a compromise, whereby linguistic elements routinely prompt a number of interpretive strategies. However, such a compromise is rarely satisfactory and often results in a weakened pragmatics, wherein what appears to be a contextual rule is in fact no more than a linguistic one, dressed up in the language of Gricean or neo-Gricean pragmatics.

Furthermore, there seems to be evidence that anaphoric pronouns are not merely interpreted in a pragmatic fug of inferencing, but are, after all, subject to certain constraints. Jones's view therefore throws too much onto context and pragmatics; after all, if there were no constraints or intralinguistic rules, we would not be able to make the right kinds of inferences.

As Heim states:

... there are data which seem to point to the existence of tighter and somehow more 'syntactic' limitations on the range of reading that actually emerge (p. 165).

Deixis is much more easily subsumed under a pragmatic theory. Traditional accounts make a distinction between the indexical and symbolic meanings of deictic terms. The symbolic meaning of a deictic term might be said to be its semantic aspect, while the indexical meaning is its pragmatic aspect.

For example, the expression *here* might be said to have a symbolic aspect roughly glossed as proximity to the speaker, while the indexical aspect would be the precise location to which *here* was referring. The terms ‘indexical’ and ‘symbolic,’ then, have much in common with the Fregean concepts of ‘reference’ and ‘sense’ (see **Sense and Reference: Philosophical Aspects; Reference: Philosophical Theories**). But the semantic aspect is so vague in certain contexts that many have felt that it cannot really be said to have any bearing on interpretation. Nunberg (1993) in particular has shown that, just as the indexical meanings of deictic terms change according to the contexts in which they occur, so too do the symbolic meanings. This breaking down of traditional binarism has had important implications for pragmatic theory. Emphasis has shifted from the meaning and reference of terms in possible contexts to consideration of the cognitive methods that addressees employ in the interpretation of utterances. Pragmatic approaches have in general attempted to blur the line between deixis and anaphora, but the tendency to see one element (deixis) as essentially exophoric and the other (anaphora) as intralinguistic remains.

Description and Prescription

G Nelson, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

In linguistics, a ‘descriptive’ approach involves, as far as possible, the objective and nonjudgmental description of language use. In contrast, a ‘prescriptive’ approach involves laying down, or prescribing, rules for correct use. The dichotomy between the two approaches most commonly surfaces in the area of grammar, though it is also relevant in other areas, such as vocabulary and phonology. The contrast between description and prescription can be illustrated in the following example: A descriptive linguist

(‘descriptivist’) will study the use of *ain’t* (as in, for instance, *I ain’t ready yet*) in terms of regional and social variation, in terms of the distribution of the usage in formal and informal contexts, and will perhaps also study the history and development of the expression. A prescriptive linguist (‘prescriptivist’) will judge the expression as constituting either ‘good’ or ‘bad’ grammar, and will condemn its use if it is seen to fail to measure up to the norms of the standard language. In the broadest terms, then, the descriptivist aims to record language, while the prescriptivist aims to shape language. However, as will be shown, the two approaches are not quite as diametrically opposed as it may appear at

first sight. The two approaches exist on the same spectrum.

For the vast majority of people, the prescriptive approach is by far the most familiar. Indeed, for most nonspecialists, the term ‘grammar’ is virtually synonymous with a set of prescriptive rules that distinguish between ‘good grammar’ and ‘bad grammar’, between the standard variety of a language and the nonstandard varieties, and between grammatical and ungrammatical expressions. In the study of the English language, prescription has had a long history, and one that continues to the present day. Indeed, almost all early grammars of English were largely prescriptive and have contributed an array of prescriptive rules with which most native speakers are very familiar. These include the following familiar axioms:

- Do not split an infinitive (e.g., *to boldly go*).
- Do not start a sentence with *and*.
- Do not end a sentence with a preposition.

Descriptivists would strongly disagree with these rules, since they have no basis in English grammar. These and other rules are the legacy of a long tradition of writing about English from a prescriptive or ‘normative’ point of view. As early as the Renaissance, many writers were concerned about foreign borrowings into English. Writing in 1561, Sir John Cheke was particularly forthright in his views: “I am of this opinion that our tung should be written cleane and pure, unmixt and unmangeled with borrowing of other tungen . . .” (quoted in Hughes, 2000: 155).

Underlying comments such as Cheke’s is a notion of ‘plain’ or ‘pure’ English, which most Renaissance commentators associated with native, Anglo-Saxon vocabulary (Jones, 1953). This may be seen as the beginning of the prescriptive tradition in English, in which writers attempted to shape the language being used by identifying – however informally – a standard to which users should aspire. For Renaissance writers, this standard corresponded to ‘purity’ or ‘propriety’ of expression.

The prescriptive approach to English reached its height during the 18th century, to such an extent that the century became known in the history of English as the ‘age of correctness’ (Leonard, 1929). The approach is best exemplified in Jonathan Swift’s *Proposal for correcting, improving, and ascertaining the English tongue* (1712). Swift proposed the establishment of an Academy for English, along the lines of the Académie Française, which would act as a final arbiter in linguistic matters. Together with many of his contemporaries, Swift felt that arbitration was needed, especially in matters of grammar and vocabulary:

Besides the Grammar-part, wherein we are allowed to be very defective, they will observe many gross improprieties, which however authorised by Practice, and grown familiar, ought to be discarded. They will find many words that deserve to be utterly thrown out of our Language, many more to be corrected, and perhaps not a few, long since antiquated, which ought to be restored. [Jonathan Swift, *Proposal for correcting, improving, and ascertaining the English tongue* (1712)]

As Swift put it, his proposal was designed to find a way of “ascertaining and fixing our Language for ever”, an aspiration that in varying degrees remains central to the prescriptive approach. For a variety of reasons – mostly political – Swift’s proposal was never acted on, and English has never had a central regulating body like the Académie Française. Instead, it has had, and continues to have, a series of more or less self-appointed authorities on the language. In the 18th century, Robert Lowth became a highly influential authority on English grammar, following the publication in 1762 of his *A short introduction to English grammar*. In the preface to his grammar, Lowth set out his prescriptive approach unambiguously:

The principal design of a Grammar of any Language is to teach us to express ourselves with propriety in that Language; and to enable us to judge of every phrase and form of construction, whether it be right or not. The plain way of doing this is to lay down rules, and to illustrate them by examples. [Lowth, 1762: x]

This is probably the clearest and most emphatic statement of the prescriptivist approach, at least insofar as it pertains to grammar. Prescriptivism is primarily didactic and regulatory. Lowth’s work is replete with examples of ‘false’ grammar, taken from literature, which he then corrects in the most unambiguous terms. Thus, for example, he takes Locke to task for his ‘improper’ use of *who*: “‘We are still much at a loss, *who* civil power belongs to’. Locke. It ought to be *whom*” (Lowth, 1762: 127). Lowth’s work did, in fact, contain a great deal of grammatical description, based on a model of Latin grammar, but it is his prescriptivism – his emphasis on identifying and expunging errors – that is his lasting legacy. His work became a standard and highly respected authority on English grammar for many decades.

In vocabulary and word meanings, the same function was performed by Samuel Johnson’s *A dictionary of the English language* (1755). In Johnson’s work, however, we see the tension between prescriptivism and descriptivism being played out in a highly perceptive way. Johnson began his work in 1747, when he published his *Plan of a dictionary*. In that work, he set out his aims and objectives, and comes across as following firmly in the prescriptive tradition. To a

large extent, he saw his role as a ‘defender’ or ‘gate-keeper’ of the language, regulating the vocabulary of English in the same way that Lowth sought to regulate its grammar. Of “barbarous or impure” words, he wrote, these “may be branded with some note of infamy, as they are to be carefully eradicated wherever they are found” (Lynch, 2002: 577). Johnson used an extensive range of usage labels, including ‘bad’, ‘barbarous’, ‘low’, ‘ludicrous’, and ‘rustick’. His prescriptivism can be seen clearly throughout his dictionary, including in the following entries:

To bamboozle v.a. A cant word not used in pure or grave writings.

To dumbfound v.a. A low phrase.

Shabby adj. A word that has crept into conversation and low writing; but ought not to be admitted into the language.

For modern readers, there is a curious tension between Johnson’s recording the use of certain words, only to prescribe that they should not be used. In these examples, and in many others, his perception of the lexicographer’s role as gatekeeper is quite clear. While on the one hand his role is to record the language, he also sees it as his duty to regulate the language, and to provide instruction to his readers. He may, in fact, have been aware of this tension himself, since in the *Plan* he alludes to his dual role: “[I]n lexicography, as in other arts, naked science is too delicate for the purposes of life. The value of a work must be estimated by its use: it is not enough that a dictionary delights the critic, unless at the same time it instructs the learner” (Lynch, 2002: 566).

Striking the balance between ‘naked science’ and didacticism remains a central problem in linguistics. In Johnson’s case, and certainly in his *Plan*, the balance is strongly in favor of the didactic, prescriptive end of the spectrum. His stated objective was to produce “a dictionary in which the pronunciation of our language may be fixed, and its attainment facilitated; by which its purity may be preserved, its use ascertained, and its duration lengthened”. His description of the lexicographer’s work in terms of military invasion and conquest constitutes one of the strongest statements of the prescriptivist position:

When I survey the Plan which I have laid before you, I cannot . . . but confess, that I am frighted at its extent, and, like the soldiers of Caesar, look on Britain as a new world, which it is almost madness to invade. But I hope, that though I should not complete the conquest, I shall at least discover the coast, civilize part of the inhabitants, and make it easy for some other adventurer to proceed further, to reduce them wholly to subjection, and settle them under laws. [Lynch, 2002: 579]

In the process of compiling the *Dictionary*, however, Johnson’s view shifted somewhat toward a more descriptive stance. A comparison between the *Plan* of 1747 and the *Preface* of 1755 is instructive in this regard, since it rehearses many of the issues that still obtain in the description/prescription debate. At one level, Johnson simply discovered the enormity of the task he had originally set himself, and realized that it was impossible to achieve. But at a deeper level, he came to recognize two important aspects of language. The first of these is the inevitability of change:

Total and sudden transformations of a language seldom happen; conquests and migrations are now very rare: but there are other causes of change, which, though slow in their operation, and invisible in their progress, are perhaps as much superiour to human resistance, as the revolutions of the sky, or intumescence of the tide. [Lynch, 2002: 41]

From this starting point, Johnson developed the idea of the inevitability of change in language, and specifically the notion of necessary innovation:

The language most likely to continue without alteration, would be that of a nation raised a little, and but a little, above barbarity, secluded from strangers, and totally employed in procuring the conveniences of life But no such constancy can be expected in a people polished by arts When the mind is unchained from necessity, it will range after convenience; when it is at large in the fields of speculation, it will shift opinions; as any custom is disused, the words that expressed it must perish with it; as any opinion grows popular, it will innovate speech in the same proportion as it alters practice. [Lynch, 2002: 41]

Johnson also came to recognize the importance of ‘general agreement’ among users of a language, as he put it, as an arbiter in linguistic matters. This led to his questioning the whole notion of authority in language, as it had been perceived by Swift and others. On a practical level, he observed that the academies of the kind Swift had proposed had been largely ineffective. They had been set up “to guard the avenues of their languages, to retain fugitives, and repulse intruders; but their vigilance and activity have hitherto been in vain; sounds are too volatile and subtle for legal restraints; to enchain syllables, and to lash the wind, are equally the undertakings of pride” (Lynch, 2002: 7).

As Johnson came to perceive it, the ultimate authority in language is invested in those who use it, or in ‘general agreement’ among the speech community. Thus he answered Swift’s concerns about obsolete words in the following way:

Swift, in his petty treatise on the English language, allows that new words must sometimes be introduced, but proposes that none should be suffered to become obsolete. But what makes a word obsolete, more than general agreement to forbear it? [Lynch, 2002: 42]

Though this was highly perceptive for its time, we should not equate Johnson's 'general agreement' with any modern concept of usage. For the most part, he invested authority in language in those literary writers that he himself considered to be the best – namely, English authors, from Philip Sidney to the Restoration, “whose works I regard as *the wells of English undefiled*” (Lynch, 2002: 36). Just as it was in the Renaissance, the notion of ‘purity’ as a linguistic ideal was still strong in Johnson's thinking about language. Perhaps the most modern expression of the authority of usage, in Johnson's own time, was made by Joseph Priestley, in *The rudiments of English grammar* (1761):

We need make no doubt but that the best forms of speech will, in time, establish themselves by their own superior excellence: and, in all controversies, it is better to wait the decisions of Time, which are slow and sure, than to those of Synods, which are often hasty and injudicious. [Priestley, 1761: vii]

Between Johnson's time and our own, fundamental changes have taken place in our perceptions of language, and especially in our understanding of language change. Today, the descriptive approach is predominant among professional linguists, many of whom often use the word ‘prescriptive’ pejoratively. However, it would be naïve to think that prescriptivism has been displaced in modern linguistics. On the contrary, it is alive and well, most notably in public perceptions of language. Indeed, the view of grammar and its didactic role that works such as Lowth's expounded is still widely held today. The reason for this is not difficult to discern: a great many people look to grammars to provide guidance, whether on general grammatical points, on writing ‘good’ English, or on matters of disputed usage. The enduring popularity of usage books is testimony to this. In the 20th century, H. W. Fowler's *Modern English usage* has remained in print, in various editions, since 1926. More recently, the phenomenal commercial success in the United Kingdom of Lynn Truss's *Eats, shoots and leaves: the zero-tolerance guide to punctuation* (2003) shows that the market for prescriptive guides is as strong as ever. In almost every case, these prescriptive guides are written by people who are nonlinguists, but who care deeply about linguistic standards. They frequently see their role as defending the language against unnecessary or unwanted change, and sometimes contrast their work with that of professional linguists. The British novelist Kingsley Amis was another in this long tradition of defenders of English, as he made clear in *The King's English: a guide to modern usage* (1997: xii): “I am sustained by reflecting that the defence of the language is too large a matter to be left to the properly

qualified, and if I make mistakes, well, so do they. . .”. Here, there is an implied criticism of professional linguists, who are perceived to have failed in some way in their responsibility to defend the language.

Most professional linguists today make a very clear distinction between prescriptive rules (which generally deal with matters of disputed usage) and descriptive rules (which generally describe matters of undisputed usage, such as subject–verb agreement). In placing the emphasis on description, they would claim that their role is to describe language in actual use, and not to prescribe how it should be used. In the field of grammar, for instance, the urge toward description has been greatly intensified in recent years through the development of corpus linguistics – that is, the use of a large, computerized database (corpus) of samples of language as the basis of study. For example, the *Longman grammar of spoken and written English* (Biber *et al.*, 1999) is based on a corpus of 40 million words of contemporary English, taken from a wide range of spoken and written sources. The *Oxford English grammar* (Greenbaum, 1996) is likewise based on a corpus of 1 million words of contemporary British English, and includes many illustrative citations drawn from sources such as private conversations, telephone calls, lectures, and business letters. In theory, at least, corpus-based grammars such as these are more ‘objective’ than, say, Lowth's, since the information they contain is not based exclusively on the grammarian's own intuitions or personal preferences, and is not shaped by his/her own subjective judgments on grammaticality and acceptability. Corpus-based grammars also recognize variation within language to a much greater degree than hitherto. By examining both speech and writing, and both formal and informal usage, the corpus-based grammars offer a more representative account of contemporary language. So as well as describing a grammatical feature, they also discuss its distribution, whether in terms of register, geography, or other sociolinguistic variables. In contemporary, descriptive grammar, the ultimate objective is to describe ‘common usage’, in a largely nonjudgmental fashion.

For some members of the general public, however, the rise of descriptive grammars, whether corpus-based or not, is often seen as an unwelcome development. From a prescriptive point of view, simply describing how people use a language is not good enough. The nonjudgmental approach adopted by the descriptivists is seen by many people as leading to the view that, in matters of usage, ‘whatever is, is right’. Parents and teachers, in particular, may view this kind of anything-goes approach as, at best, unhelpful, and, at worst, irresponsible. This is often because it appears to many people that grammarians who refuse to be

judgmental are denying the existence of standards altogether, and are refusing to make the crucial distinction between ‘good’ uses of language and ‘bad’ uses of language. For the prescriptivists, the grammarian’s role in particular should be to make this distinction clear, just as it was for Lowth, so that in learning grammar, their children will learn, specifically, *good* grammar, and thereby develop their literacy skills.

The descriptivists and the prescriptivists have been poles apart for much of the 20th century. The distance between the two approaches is well illustrated in a recent (prescriptive) publication about standards of English, entitled *Lost for words: the mangling and manipulation of the English language* (2004), by the British Broadcasting Corporation journalist, John Humphrys. Among other recent developments in English, Humphrys condemns the loss of the apostrophe in the word *let’s*, in cases in which it has singular reference only (as in, *Let’s give you a hand*). He takes the professional (descriptive) linguist Jean Aitchison to task for her comments about this, in her book *Language change: progress or decay?* Taking a long-term view of language change, Aitchison described the loss of the apostrophe in *let’s* in terms of grammaticalization, and continued with “*Let’s*, perhaps now better spelled *lets*, is used as a simple exhortation, and is no longer thought of as a verb plus a pronoun” (Aitchison, 2001: 113). Taking a strongly prescriptivist stance, Humphrys (2004: 35) comments: “Can this be true? A respected academic condoning such vandalism?” He goes on to consider whether a sentence such as *I could of danced all night* will also be dismissed in the same way, as something that can be explained in terms of grammaticalization, and is therefore ‘condoned’, on that basis, by the descriptivists. He concludes: “Far from liberating the young, this sort of nonsense is more likely to harm them” (Humphrys, 2004: 36).

Of course, both sides in this debate have legitimate points to make, in their own terms. However, these points seem to be irreconcilable, because the ultimate objectives of each side are quite distinct. The objectives of the prescriptivists are short-term, immediate, and practical. They aim to provide clear-cut guidance for the general user of language. Their approach is motivated by a well-intentioned desire to maintain standards of literacy and to teach young people, in particular, the differences between good uses of language and bad uses of language. Few if any people – whether descriptivists or prescriptivists – could argue with this objective. On the other hand, the approach followed by Aitchison and other descriptivists is also legitimate, in its own terms. The objective here is to explain grammatical change over time, and in the context of broader linguistic processes, but it stops

short of evaluating that change in any way. The two approaches also address quite different audiences: the prescriptivists write for nonspecialists, whereas the descriptivists, in general, write for fellow linguists. As we saw, Johnson identified this dichotomy quite early on: it is the ever-present dichotomy in language studies between ‘usefulness’ and ‘naked science’.

Can anything be done to bridge the gap between these two approaches? The first point to consider is that the descriptive approach is not, in reality, quite as objective or as ‘scientific’ as we might be led to believe. Even descriptive grammarians make implicit value judgments about their material, and they will be influenced by their own intuitions about the language. In selecting a particular sentence, for instance, to illustrate a grammatical point, the grammarian is implicitly labeling it as ‘grammatical’, in contrast with the infinite number of ungrammatical sentences. In generalizing from observed corpus data, native-speaker grammarians, in particular, will often rely on their own judgments of acceptability. In writing the descriptive *Comprehensive grammar of the English language* (Quirk *et al.*, 1985), the authors freely admitted that “in the absence of sufficient evidence our evaluations sometimes relied on our own experience and feelings” (Greenbaum, 1988: 34–35). Indeed, the authors of that grammar also took account of the prescriptive tradition, on the grounds that it has had an impact on the language that people use, especially in the most formal contexts. They recommend that grammarians “should take account of prescriptive grammar in their descriptive grammars, since prescriptive norms affect use...” (Greenbaum, 1988: 34). In descriptive, corpus-based grammars, the selection of samples to include in the corpus may also be influenced by subjective or evaluative judgments. In dictionaries, too, usage labels such as ‘informal’ or ‘formal’ are frequently applied to words. Although these are less evaluative than those used by Johnson, they do provide evidence of the lexicographer making judgments about words on the basis of a perceived standard. The supposed objectivity of the descriptive approach is also called into question when we consider that all description is influenced, to some degree, by language theory, of whatever persuasion. The notion of a ‘theoretically neutral’ description of a language is more an ideal than a reality. In whatever subfield the linguist works, an entirely objective description of a language is rarely if ever achieved.

The second, more crucial point is the charge, implicit or explicit, that in adopting a descriptive approach, linguists are in some way shirking their responsibility to ‘defend’ language, or to maintain standards. Although few if any linguists today would see their role in this light, this is an important

issue because it determines public perceptions of linguistics. In *Good English and the grammarian*, Sidney Greenbaum considers this issue, and proposes that professional grammarians should become actively engaged in public discussions about usage, bringing their professional training to bear on points of disputed usage. Recognizing that the term 'prescriptivism' is often used pejoratively by linguists, he suggests that the term 'language planning' should be used instead: "Let us then say that grammarians have a responsibility to be language planners" (Greenbaum, 1988: 38). According to Greenbaum, language planners have a crucial role to play, particularly in areas in which no national standard has yet been established, such as in the nonnative Englishes that are emerging in some postcolonial African and Asian countries. In general, Greenbaum does not see a radical dichotomy between descriptivists and prescriptivists. Although they may be very different in terms of their views of language, their objectives, and the audiences they address, the two can come together in that the results of academic linguistic research will eventually filter down to pedagogic grammars and textbooks: "Scholarly grammars have a limited readership, but they eventually influence lower-level grammars, textbooks, and other teaching material, for native students and (in particular) for foreign students" (Greenbaum, 1988: 36).

Descriptions, Definite and Indefinite: Philosophical Aspects

G Ostertag, Nassau Community College, Garden City, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Definite descriptions in English take one of two forms: as the definite article *the* concatenated with a nominal (e.g., *table*, *husband*, *game*) or as either a possessive adjective (*her*, *my*) or noun phrase (*everyone's*, *John's*) concatenated with a nominal. Thus, *the table*, *her husband*, *everyone's favorite game*, *my cat*, and *John's bicycle* are all definite descriptions. In contrast, indefinite descriptions take a single form:

as the indefinite article *a* (or *an*) concatenated with a nominal. Examples of indefinite descriptions are *a table*, *an employee*, *a thing I haven't mentioned*, *a friend of Mary's*. Although this classification is not perfect – *the friend of an acquaintance*, although intuitively indefinite, comes out as definite – it conforms to usage standard among philosophers, logicians, and linguists.

According to Bertrand Russell, descriptions – both definite and indefinite – are devices of quantification. That is, both *the F is G* and *an F is G* can be interpreted as expressing a relation between the properties F and G. Since Russell's treatment is by far

the most influential approach to descriptions in the philosophical literature, this entry will focus on his views. It begins by briefly reviewing the motivations behind Russell's mature view on descriptions, which stem in part from inadequacies of his earlier approach, and proceeds to a statement of Russell's mature view. Challenges to this view are then considered, as are alternative proposals.

Russell's Theories of Description

Russell's Early Theory of Denoting

Intuitively, an utterance of the singular sentence *I met Tony Blair* expresses a proposition that, among other things, is about Tony Blair. In virtue of what does this relation of 'aboutness' hold? For Russell, *circa The principles of mathematics* (1903), the proposition that I met Tony Blair is about Mr Blair by virtue of containing him as a constituent. This in turn suggests an answer to a related question, namely, What is the contribution of the expression 'Tony Blair' to the aforementioned proposition? Russell identifies the contribution 'Tony Blair' makes to this proposition with the constituent that enables it to be about Tony Blair – namely, the individual Tony Blair himself (*see* **Direct Reference**).

How are we to understand the parallel contribution the syntactically complex denoting phrase *a man* makes to the proposition *I met a man*? Russell's answer was that it contributes, not an individual, but a certain complex concept – what he called a 'denoting concept.' Russell conceived of a denoting concept by analogy with what he called a 'class concept' (roughly, a property or condition that determines a class of entities). Whereas the nominal *man* contributes a class concept to the proposition that I met a man, the complex phrase *a man* contributes a denoting concept. However, as Russell noticed, denoting concepts possess a puzzling combination of features. For one, the relation between the denoting concept and its denotation is, as he later put it, 'logical,' and "not merely linguistic through the phrase" (Russell, 1905: 41). That is to say, the denoting concept denotes what it does because of something intrinsic to the denoting concept itself, not because of any facts attaching to the denoting phrase that expresses it. Second, a denoting concept is an 'aboutness-shifter' (Makin, 2000: 18). Although the denoting concept associated with *a man* is a constituent of the proposition *that I met a man*, the denoting concept is not what this latter proposition is about.

Third, denoting concepts fail to conform to a principle of compositionality, according to which the meaning of a complex expression is a function of its

structure and the meanings of its constituents (*see* **Compositionality: Philosophical Aspects**). Russell was keenly aware of this deficiency. He remarked that *all men* and *all numbers* seem to be analyzable into a concept associated with the determiner *all* and the respective class concepts *men* and *numbers*, continuing:

But it is very difficult to isolate any further element of *all-ness* which both share, unless we take as this element the mere fact that both are concepts of classes. It would seem then, that "all *u*'s" is not validly analyzable into *all* and *u*, and that language, in this case as in some others, is a misleading guide. The same remark will apply to *every*, *any*, *some*, *a*, and *the*. (Russell, 1903: 72–73)

The inability of the theory of denoting concepts to reflect the compositional nature of denoting phrases is a serious defect of the approach. Not only does surface grammar overwhelmingly suggest that *all men* and *all numbers* possess a common semantic feature; in addition, speakers familiar with the nominal *curator* and with the determiner *all* will understand sentences containing *all curators* in subject position (assuming familiarity with the other expressions), even supposing they have never come across that particular combination. An acceptable theory of denoting phrases cannot leave this phenomenon unexplained.

Russell's Mature Theory

Russell (1905) developed an approach to denoting phrases that avoided each of the difficulties noted above. His revision makes use of the doctrine of contextual definition, or 'meaning in use,' dispensing with the idea that denoting phrases can be assigned meanings 'in isolation.' Rather, each of the aforementioned denoting phrases is defined within its sentential context. While the treatment of indefinite descriptions, if not wholly uncontroversial, is straightforward (*an F is G* is defined as *something is both F and G*), the treatment accorded definite descriptions is rather less intuitive: *the F is G* is defined as *something is both uniquely F and G*. This is equivalent to the conjunction of three claims: *something is F*; *at most one thing is F*; *every F is G*. It can be seen that, in this analysis, *the F is G* will be false if either nothing is F, more than one thing is F, or some F is not G.

Definite Descriptions in *Principia mathematica*

Russell's favored expression of the theory of descriptions is in the formal language of *Principia mathematica*, where the theory is rendered as follows:

$$(R1) \quad G(\iota x)Fx =_{\text{def}} \exists x(\forall y(Fy \equiv y = x) \ \& \ Gx)$$

The definiens is the formal analogue of *the F is G*, with the *iota* phrase corresponding to the definite article; the definiendum is the formal analogue of the sentence *something is both uniquely F and G*. As the definition shows, the surface grammar of $G(\iota x)Fx$ is misleading with respect to its logical form. While $(\iota x)Fx$ takes singular term position, its logical role is not that of a singular term (that is to say, unlike a singular term, it does not even purport to refer). Indeed, given the logical law $\tau = \tau$, taking descriptions to be singular terms allows the derivation of $(\iota x) (Fx \ \& \ \neg Fx) = (\iota x) (Fx \ \& \ \neg Fx)$; this in turn allows the further derivation of the absurdity $\exists x \ x = (\iota x) (Fx \ \& \ \neg Fx)$. (Note that logical systems permitting empty singular terms do not license the second inference; see Lambert, 2003.)

Russell's theory, as encapsulated in R1, avoided the difficulties that plagued the doctrine of denoting concepts: their mysterious ability to determine their denotations logically; their disruption of the aboutness-as-constituency doctrine; and their failure to conform to a principle of compositionality. (It also enabled Russell to explain how a sentence containing a non-denoting description can nonetheless be meaningful.) Since the denoting phrase $(\iota x)Fx$ disappears under analysis, and since the analysans introduces no new denoting phrases, the first two difficulties no longer arise. In addition, R1 shows how every context in which $(\iota x)Fx$ occurs can be replaced with a context that is fully compositional (although the fact that R1 puts logical form at variance with surface grammar has led some to question its usefulness in a compositional semantics for English).

Descriptions and Scope

R1 shows how to eliminate sentences containing $(\iota x)Fx$ and replace them with sentences containing only the familiar logical vocabulary of variables, predicate constants, connectives, and quantifiers. But the definition fails to provide a unique replacement strategy for sentences such as $G(\iota x)Fx \supset p$. Both of the following are consistent with our definition:

$$(1a) \ \exists x(\forall y(Fy \equiv y = x) \ \& \ (Gx \supset p))$$

$$(2a) \ \exists x(\forall y(Fy \equiv y = x) \ \& \ Gx) \supset p$$

The former corresponds to the reading in which the scope of $(\iota x)Fx$ is $G(\iota x)Fx \supset p$, and the latter corresponds to the reading in which the scope of $(\iota x)Fx$ is $G(\iota x)Fx$ (see **Scope and Binding: Semantic Aspects**). Russell's contextual definition of $(\iota x)\Phi x$ in *Principia mathematica* employs an awkward but effective device to eliminate such structural ambiguities:

$$(R2) \ [(\iota x)\Phi x] \ \Psi(\iota x)\Phi x =_{\text{df}} \exists x(\forall y(\Phi y \equiv y = x) \ \& \ \Psi x)$$

The scope of $(\iota x)\Phi x$ is determined by the placement of $[(\iota x)\Phi x]$. The general rule is that the scope of an

occurrence of $(\iota x)\Phi x$ is the entire context to which the scope operator $[(\iota x)\Phi x]$ is prefixed. Using Russell's notation, the readings corresponding to (1a) and (2a) are represented as (1b) and (2b):

$$(1b) \ [(\iota x)Fx] \ (G(\iota x)Fx \supset p)$$

$$(2b) \ [(\iota x)Fx] \ G(\iota x)Fx \supset p$$

Recent developments in syntactic theory provide a more natural method of indicating scope (see May, 1985). What Russell referred to as 'denoting phrases' are, in fact, natural language quantifiers. Since such quantifiers are invariably restricted, the most natural way to represent them is not in first-order logic – the language of *Principia mathematica* – in which quantifiers are unrestricted, but rather in a language permitting restricted quantification. In such a language, a quantifier is the result of concatenating a determiner, subscripted with a variable, with a formula (for example, $[\text{some}_x: x \text{ is human}]$). As with unrestricted quantification, the resulting expression can itself combine with a formula to create a sentence. This allows us to express *the F is G* as $[\text{the}_x: Fx] (Gx)$. Instead of the serviceable but unwieldy (1b) and (2b), we get (1c) and (2c), which are far more natural renderings of the respective contexts:

$$(1c) \ [\text{the}_x: Fx] (Gx \supset p)$$

$$(2c) \ [\text{the}_x: Fx] (Gx) \supset p$$

Note that in this interpretation, descriptions, like quantified noun phrases generally, can be assigned meanings in isolation. Just as the quantifier *all kings* denotes the set of properties possessed by all kings $[\lambda P \ \forall x(\text{King}(x) \supset Px)]$ and *some kings* denotes the set of properties possessed by some kings $[\lambda P \ \exists x(\text{King}(x) \ \& \ Px)]$, the definite description *the king* denotes the set of properties possessed by something which is uniquely king $[\lambda P \ \exists x(\forall y(\text{King}(y) \equiv y = x) \ \& \ Px)]$. In this approach, *the king is bald* is true just in case being bald is among the properties the king possesses. (For details see Westertahl, 1986.)

This machinery pays off handsomely, disambiguating contexts involving the interaction of descriptions with modal operators and with verbs of propositional attitude (see **Modal Logic; Propositional Attitude Ascription: Philosophical Aspects**). In addition, it clarifies the relation between surface grammar and logical form, something that R1 leaves obscure.

Responses to Russell's Theory of Definite Descriptions

Strawson's Critique of Russell

For almost half a century, Russell's theory maintained the status of orthodoxy. But in an article published in

Mind in 1950, the Oxford philosopher P. F. Strawson launched an influential attack. The attack focused on Russell's alleged disregard for ordinary usage, a disregard manifested in Russell's assumption that for every well-formed sentence-type *S* there exists a unique proposition expressed by *S*. In fact, Strawson noted, the same sentence can be used on one occasion to assert one proposition, on a different occasion to assert another proposition, and on a third to assert nothing at all. In order to maintain his view, Russell is forced to provide what amounts to a logical guarantee that in even the least propitious situation a sentence would, however implausibly, possess a definite truth-value. To ensure that *the F is G* expresses a proposition come what may, Russell interpreted it as a complex existential claim, rejecting the intuitive classification of *the F* as a singular term. Strawson claimed that this analysis is contradicted by common usage. If Russell were correct, then the proper response to *The present king of France bald. Is this true?* would be a firm *no*. In fact, the proper response would address the belief betrayed by the utterance, that is, that France is at present a monarchy.

Strawson claimed that to understand the linguistic meaning of an abstract sentence-type *S* requires mastery of the 'rules of use' associated with *S*. In the case of *the present King of France is wise*, the rules require that it be used only when France is a monarchy. To use this sentence seriously and literally is, among other things, to present oneself as believing that the relevant conditions are fulfilled. If, in fact, the belief is false, then the utterance fails to express a proposition – it is something about which 'the question of truth does not arise.'

Yet Strawson's own theory is open to the following challenges. (1) It is not at all clear that utterances containing vacuous descriptions are devoid of propositional content. A contemporary utterance of *yesterday Mick Jagger met the King of France* is, *contra* Strawson, intuitively false. (2) The proposal fails to apply in any obvious way to relational descriptions bound by a higher quantifier. The description *each girl's mother* in (3a) is properly unpacked as *the mother of x*, with the variable bound by the quantifier *each girl*. This is made explicit in (3b):

(3a) Each girl's mother attended.

(3b) $\forall x(Gx \supset A(ry)Myx)$

How such descriptions can be said to refer is a mystery. While there are formal responses to this worry, they are far from being intuitively satisfying (Evans, 1982: 51–57).

Finally, it should be noted that Strawson partly misrepresented Russell's actual view, or at least provided an unnecessarily inflexible interpretation

of it. For example, Russell could happily incorporate the distinction between sentence and utterance that Strawson accused him of overlooking. Indeed, Russell himself provided the context-sensitive expression *my only son* as an example of a description, indicating an awareness that different tokens of the same sentence may express different propositions. This reveals something Strawson failed to recognize: that the distinction has no direct bearing on the question of the logical form of description sentences. Contemporary Russellians, such as Stephen Neale (1990), accept the distinction, seeing in it no fundamental challenge to Russell's theory.

The Ambiguity Thesis

Keith Donnellan (1966) described a phenomenon that neither Russell nor Strawson had considered: that *the F* can be used to refer to a nonF. Donnellan gave as an example an utterance of *Smith's murderer is insane*, made in court on observing the bizarre behavior of a man (call him Jones) accused of murdering Smith. Even if the description 'fits' someone else, Donnellan claims, the utterance clearly refers to Jones, and not the actual murderer, whoever that might be.

But as Saul Kripke (1977) observed, appeals to usage alone cannot contradict Russell's theory. One can use a sentence to communicate a proposition that departs from its literal meaning, so data about usage are in themselves insufficient to mount a successful challenge to Russell (see **Referential versus Attributive**). What is needed is a decisive intuition that, in the imagined utterance, the speaker literally states that Jones is insane. Such an intuition would strongly favor the thesis that definite descriptions are ambiguous between a nonRussellian, 'referential' use and a Russellian, 'attributive' use. Yet few theorists are ultimately willing to commit to the view that, in the imagined utterance, the speaker has literally stated that Jones is insane.

A related argument, due initially to Strawson, provides a much stronger challenge. Utterances of description sentences typically exhibit incompleteness. That is, while the nominal is true of a plurality of objects, the speaker intends nonetheless to speak truly. For example, a librarian issues a polite reminder to a patron by uttering *the book is overdue*. For Russell, this utterance is true just in case there is exactly one book, and any book is overdue. This seems to get things wrong, as the librarian is clearly not intending to say – and is not taken to be saying – something that is, as things are, blatantly false.

Though some have argued that, intuitions notwithstanding, the utterance is, strictly speaking, false, few have found this idea appealing (but see Bach, 1988).

Russellians have responded by claiming that the context of utterance can be relied on in such cases to provide the missing completing material. Thus, what the librarian intends to convey is perhaps that *the book you borrowed last month is overdue* or that *the book you just mentioned is overdue*, and so on. Of course, the suggestion leads immediately to a worry. Typically, when a speaker utters a sentence containing a contextually incomplete description, there will be a multiplicity of completing properties to choose from. The question, Which completion is the one that both the speaker intended to convey and the hearer took the speaker to have intended? can receive no definite answer. And yet, such utterances are not typically accompanied by any indeterminacy or uncertainty as to what was said.

Incomplete descriptions are used almost invariably to refer to a contextually definite object – in our example, to a particular book. In such cases, the speaker succeeds in communicating a proposition containing (or somehow about) the entity in question. Given that such sentences are typically used to communicate just such ‘referential’ propositions, Howard Wettstein (1981) has suggested that in such contexts, a speaker literally asserts the relevant referential proposition. This hypothesis is, after all, consistent with the fact that the librarian’s utterance was perfectly determinate, whereas the Russellian hypothesis, sketched above, is not.

Of course, there remains the case of non-referentially-used incomplete descriptions: for example, *the murderer is insane*, uttered at the scene of a brutal murder and without knowledge of the murderer’s identity. Wettstein’s suggestion is useless here. After all, such uses cannot be supposed to express referential propositions, since there is no referent. But to suppose, with Wettstein, that context provides completing information in such cases is no more plausible here than in the referential case.

Responses to Russell’s Theory of Indefinite Descriptions

Referential Uses of Indefinite Descriptions

As we have seen, Russell defines *an F is G* in terms of the existential quantification, *something is both F and G*. As with definite descriptions, indefinite descriptions are often used referentially. Moreover, the relevant data seem open to the same response – that facts about usage cannot, by themselves, allow one to draw conclusions about literal meaning. But, as in the previous cases, matters are not so simple. Consider (4):

- (4) There’s a man at the door. He’s selling linguistics encyclopedias.

If Russell is correct, then the first sentence asserts that at least one man is at the door. But how then are we to understand the second sentence? After all, intuition suggests overwhelmingly that the pronoun refers to the individual introduced by the indefinite ‘a man.’ Doesn’t this force us to conclude that the indefinite is likewise referential? Not necessarily: as Lewis (1979: 243) noted, “What I said was an existential quantification; hence, strictly speaking, it involves no reference to any particular man. Nevertheless it raises the salience of the man that made me say it.” And this fact allows a subsequent pronoun to make literal reference to the man.

This seems to settle the question in favor of Russell. But an example due to Michael Devitt raises a further difficulty for his theory:

Several of us see a strange man in a red baseball cap lurking about the philosophy office. Later we discover that the Encyclopedia is missing. We suspect that man of stealing it. I go home and report our suspicions to my wife: “A man in a red baseball cap stole the Encyclopedia.” Suppose that our suspicions of the man we saw are wrong but, “by chance,” another man in a red baseball hat, never spotted by any of us, stole the Encyclopedia. (Devitt, 2004: 286)

In Russell’s theory, the utterance comes out as true; Devitt claims that it is false. But Devitt’s intuition seems mistaken. If the speaker uses the quoted sentence referentially, then his utterance is successful only if his audience in some way grasps the referential proposition intended. In other words, if the utterance is referential, it cannot be understood unless the audience has cognitive contact of some sort with the referent. Yet it seems clear that the hearer can fully understand the utterance even without any such contact with the speaker’s referent. So, it would seem, the case against Russell fails. (See further Ludlow and Neale, 1991.)

An Alternative Nonreferential Account

Recently, theorists have considered a third option: that indefinites lack “quantificational force of their own” (Chierchia, 1995: 11). In this view, an indefinite description is not a quantifier, nor is it a referring expression. Rather, it resembles a free variable in that it can be bound by a quantifier that c-commands it, with the significant difference that, when not c-commanded by a quantifier, it is interpreted as bound by an existential quantifier (on c-command, see *Scope and Binding: Semantic Aspects*). For example, consider (5a):

- (5a) Whenever a man owns a donkey, he beats it.

Here, *whenever* has universal force, binding any free variables within its scope. This reading is captured in (5b):

- (5b) $\forall x, y (\text{man}(x) \ \& \ \text{donkey}(y) \ \& \ \text{owns}(x, y) \supset \text{beats}(x, y))$

A variant of this example – *if a man owns a donkey, he beats it* – receives the same analysis since, in the view in question, when an *if* clause lacks an overt quantifier, an unrealized universal quantifier is assumed to be present.

As indicated, when an indefinite is not within the scope of a quantifier, it is interpreted as bound by an existential quantifier:

- (6a) Whenever a man owns a donkey, he beats it with a stick.
 (6b) $\forall x, y ((\text{man}(x) \ \& \ \text{donkey}(y) \ \& \ \text{owns}(x, y)) \supset \exists z (\text{stick}(z) \ \& \ \text{beat-with}(x, y, z)))$

The analysis yields some counterintuitive results, however. Consider:

- (7a) If Mary finds a copy of *Middlemarch* at Bookworms, she'll buy it.
 (7b) $\forall x ((\text{copy-of-Middlemarch}(x) \ \& \ \text{finds-at}(\text{Mary}, x, \text{Bookworms})) \supset \text{buys}(\text{Mary}, x))$

In the suggested analysis, this sentence is true just in case Mary buys *every* copy of *Middlemarch* she finds at Bookworms. But, intuitively, it can be true if, finding several copies, Mary, sensibly, buys just one.

One recent response to this difficulty is to take indefinites as introducing a choice function – that is, a function from a predicate *P* to a specific member of *P*'s extension (see Reinhart, 1997). Informally, the choice-function analysis of the previous example is as follows: for some choice function *f*, Mary buys *f*(copy-of-*Middlemarch*(*x*) & finds-at(*Mary*, *x*, Bookworms)). This captures the desired truth conditions, but it seems unintuitive as an account of the literal meaning of the relevant sentence. It might, for example, be objected that speakers assertively uttering (7a) do not take themselves to be referring to, or quantifying over, functions; but this is precisely what the analysis implies.

There is, it should be added, a competing Russellian account in the literature, according to which unbound anaphora are concealed definite descriptions. This view has the potential to provide a truth-conditionally-adequate approach to the data without the awkward commitments of the current approach. (See Neale, 1990: chapters 5 and 6; also see **Anaphora: Philosophical Aspects.**)

Direct Reference

A Sullivan, Memorial University of Newfoundland,
St. John's NL, Canada

© 2006 Elsevier Ltd. All rights reserved.

What Is Direct Reference?

Let us begin with a brief introduction to some essential terms. A *singular term* is an expression whose role is to specify a particular individual – proper names (e.g., ‘John’) and pronouns (e.g., ‘she’) are paradigm cases. A *proposition* is the meaning expressed by a sentence. A sentence whose subject-expression is a singular term (e.g., ‘John is tall,’ ‘She is happy’) expresses a *singular proposition*. (In contrast, a sentence whose subject-expression is a general term expresses a *general proposition* [e.g., ‘Tigers are mammals’].)

Direct reference is a contrastive term; the contrasting view is ‘mediated’ or ‘indirect’ reference. (For brevity, I’ll use the labels ‘DR’ for the former and ‘IR’ for the latter.) The classic IR position is developed by Frege (1892). On Frege’s view, terms express a sense that determines a referent. All IR views posit some such semantic mediator between words and referents, and the characteristic virtue of the IR approach is that it affords a clear explanation of how co-referential terms can differ in meaning. (For other examples of influential IR views, see Carnap [1947] and Searle [1983].)

One finds a very different approach to the semantics of (at least some) singular terms in the work of Mill and Russell. However, even though both Mill (1843: 20) and Russell (1919: 283) use the expression ‘direct’ in relevant contexts, the term ‘direct reference’ was first explicitly coined, and given a precise sense, by Kaplan (1977: 483). On Kaplan’s usage, DR expressions do not conform to one particular tenet of the IR approach, according to which the semantic mediator, the sense or the manner in which the term presents its referent, is a constituent of the proposition expressed. Kaplan’s (1977) central thesis is that indexical expressions (such as ‘I,’ ‘yesterday,’ or ‘that duck’) are DR. He also suggests (1977:

558–563) that proper names are DR. A central component of Kaplan’s picture is an account of a kind of meaning he calls ‘character’ (1977: 505–507), which is intended to explain why it seems that co-referential DR terms can make distinct contributions to propositional content.

The heart of Kaplan’s notion of DR is Russell’s criterion for individuating singular propositions: “A name is merely a means of pointing to the thing, and does not occur in what you are asserting, so that if one thing has two names you make exactly the same assertion, whichever of the names you use...” (Russell, 1918: 245). If a term is DR, in Kaplan’s sense, then the propositions expressed by sentences in which it figures are individuated solely in terms of the individuals and properties that they are about, as opposed to in terms of more finely grained senses or concepts. Because the contribution a DR term makes to propositional content is its referent, sentences that differ only in the interchange of co-referential DR terms express the same proposition.

The difference between the DR and IR views, then, is most stark concerning such pairs of sentences – e.g., ‘That [pointing to the heavens] is Mars’ versus ‘Mars is Mars.’ On the IR view, there is a clear difference between the propositions expressed by such pairs of sentences; for one has as a constituent the meaning or sense of ‘that,’ whereas the other has as a constituent the meaning or sense of ‘Mars.’ However, the price paid is that IR views posit mediators between terms and referents, and critics allege that these mediators create more problems than they solve. On the DR view, there are no semantic mediators – no senses or concepts – involved in the content of a singular proposition; proponents of the view argue that this affords a more satisfactory account of the content and truth-conditions of such propositions. (That is, singular propositions are about the relevant referents *per se*, not about whatever might happen to satisfy a certain sense or concept.) However, the DR view allows no room for the intuition that such pairs of sentences can express distinct propositions: if ‘that’ and ‘Mars’ are co-referential, there is

no semantic difference between the propositions expressed by sentences which differ only in their interchange. (See later for more on this difference, and its consequences.)

Recanati (1993) is an important subsequent work on DR. (Recanati is heavily influenced by the works of Perry, collected in Perry [1993].) In the interim, Evans (1982) and McDowell (1986) had spurred a neo-Fregean approach to singular terms by arguing that many criticisms of Frege's views can be met if senses are conceived as object-dependent (and so 'rigid,' in Kripke's [1972] terminology). Recanati defines DR terms as those with a semantic feature that indicates that the truth-condition expressed by sentences containing them is singular or object-dependent, and argues that this gets to the core of the difference between referring expressions (such as names and indexicals) and quantified noun phrases (such as 'a man' or 'all Texans'). Recanati's notion of DR is weaker than Kaplan's, in that neo-Fregean singular terms (which express object-dependent senses) would be classified as DR in Recanati's sense but not in Kaplan's (because object-dependent senses figure as constituents of propositions for Recanati, which is inconsistent with Kaplan's Russellian criterion for individuating propositions). On Recanati's view, as distinct from Kaplan's, sentences that differ only in the interchange of co-referential DR terms, although truth-conditionally equivalent, express distinct propositions.

Neither Kaplan nor Recanati deny that DR expressions are semantically associated with something like a sense or manner of presentation. (This can hardly be denied for indexicals.) What Kaplan explicitly denies, in calling an expression DR, is that the sense or manner of presentation affects propositional content. What Recanati explicitly denies is that the sense or manner of presentation is truth-conditionally relevant. So, strictly speaking, the contemporary authorities use 'direct reference' to label an approach to propositional content, more so than as a label for any specific approach to reference.

Some Closely Related Concepts

Kaplan's DR is a part of an anti-Fregean tide that swept the philosophy of language in the 1970s. In much of the secondary literature, the distinction between DR and other aspects of that movement – such as the causal-historical theory of reference, the notion of rigid designation, and the Millian view of proper names – is lamentably blurred. It is not uncommon to find a bundle of such notions lumped together under the umbrella term 'the new theory of reference.' The aim of this section is to be more discriminating about

the relations between DR and these other concepts and views.

The Millian view has it that names are connotationless labels: "A proper name is but an unmeaning mark which we connect in our minds with the idea of the object..." (Mill, 1843: 22). This is no mere claim about truth-conditions; it is a very strong claim about the semantics of names. Mill even says that: "The name, therefore, is said to signify the subjects *directly*..." (1843: 20). Nonetheless, it is clear that Mill's notion of direct reference is quite distinct from Kaplan's. Witness the fact that indexical expressions (e.g., 'I,' 'yesterday') are the very paradigm of DR for Kaplan, but are clearly not unmeaning marks. Kaplan (1977: 520) discusses this "drawback to the terminology 'direct reference'" – that it "suggests falsely that the reference [of an indexical] is not mediated by the meaning, which it is." Explicitly, Kaplan (1989: 568) does not deny that DR terms are semantically associated with something like a sense. What he denies is that the sense is a propositional constituent.

In the case of proper names, though, this conflation of DR with the Millian view is more prevalent, and more difficult to rebut. One reason is that there are strong considerations against the view that names are semantically associated with a particular semantic mediator (see especially Donnellan [1970] and Kripke [1972]). So, in the case of names, as compared with indexicals, it is more difficult to identify anything that plays a semantic role akin to Kaplan's character, singling out the referent without affecting propositional content. Hence, although it is implausible to hold that indexicals are Millian (even if they are DR), it is not uncommon to encounter the idea that names are Millian (i.e., a name's meaning is just its referent) and that names are DR (i.e., a name's contribution to propositional content is just its referent) are two sides of the one coin. However, to the contrary, there is clearly conceptual space for the view that proper names are DR but not Millian (i.e., names are semantically associated with some kind of sense or meaning, but nonetheless that sense or meaning is truth-conditionally irrelevant, no part of propositional content).

Although a term could clearly be DR without being Millian, it is plausible that if a term is Millian then it is DR. That is, if all that there is to the semantics of a term is that it labels a specific referent, then it is hard to see what else but the referent could affect propositional content. A similar relation holds between Kaplan's DR and Kripke's (1972) rigid designation. (A designator is rigid if it designates the same thing in every possible world.) There are clearly rigid designators that are not DR (say, 'the even prime'), but nonetheless any DR term will satisfy the criterion

for rigidity (see Kaplan [1977: 492–498, 1989: 569–571]). So, there are rigid terms that are not DR, and DR terms that are not Millian; but any Millian term would be DR, and all DR terms are rigid.

There is a nice fit between the semantics of DR and the causal-historical story of how reference is determined. Donnellan's (1970) and Kripke's (1972) influential arguments that the meaning of a proper name is not some kind of descriptive sense have been taken to demonstrate, or to suggest, general and fundamental problems with any IR approach to names. From here, it looks compelling to conclude that a name's contribution to propositional content is just its referent. Furthermore, it is possible that appeal to distinct causal-historical chains of transmission can explain why it seems that co-referential names differ in meaning. (More on this later.)

In any case, the present point is just that these are all are distinct doctrines, addressed to quite different questions. The Millian view is a bold conjecture about the semantics of names, DR is a somewhat weaker claim about propositional content, rigid designation is a still weaker modal claim about certain terms, and the causal-historical theory is a picture of how reference is determined. There are deep and interesting relations between these concepts and views, but they should not be conflated.

Problems with Direct Reference

The classic problems for DR are, not surprisingly, the very problems that led to the development of the IR view in the first place. The central problem concerns questions of substitutivity – that is, there are reasons to think that interchanging co-referential expressions fails to preserve propositional content. Substitutivity arguments against the DR view of names have been part of the canon since Frege (1892). Competent speakers can fail to recognize that co-referential names do in fact name the same object, and so sentences that differ only in the interchange of co-referential names seem to express distinct propositions. Clearly, similar things can happen with indexicals. Consider, for example, Kaplan's (1977: 537) case wherein he sees a reflected image of a man whose pants are on fire, then subsequently come to recognize that he is that man. Even though his initial 'His pants are on fire' and subsequent 'My pants are on fire' are truth-conditionally equivalent, there are significant semantic differences between them.

So, the DR theorists need to accommodate the considerable reasons for thinking that sentences that differ only in the interchange of co-referential terms can express distinct propositions. Alternatively put, although the IR view issues in more finely grained

propositions, which are better suited to capture the content of a belief, the DR view issues in propositions which are too coarsely grained for this purpose. (For example, believing that 'His pants are on fire' and believing that 'My pants are on fire' would prompt different actions; insofar as the DR view is committed to the claim that these beliefs have the same content, then, something is amiss.)

Kaplan's (1977) notion of 'character' is intended to solve this problem for the case of indexicals – i.e., to explain the differences between 'His pants are on fire' and 'My pants are on fire,' in a way that is consistent with the semantics of DR. The extent to which Kaplan's account is successful is one of the central points of controversy in the subsequent literature on this topic. Note also that there are cases, first raised by Perry (1977), which character cannot accommodate. The cases concern two uses of the same demonstrative – and so character remains constant – wherein, unbeknownst to the speaker, the same individual is referred to twice. (For instance, a speaker utters 'This ship (pointing to the stern of a ship through one window) is American but this ship (pointing to the bow of a ship through a different window) is Japanese.') Kaplan (1977: 514ff) makes some effort toward accommodating this kind of problem, but his remarks are sketchy, and have been contested. (Cf. Braun [1994] for discussion, and King [2001] for an overview of the burgeoning literature.)

In the case of names, DR theorists have drawn on the causal-historical theory of reference to explain why it seems that co-referential names differ in meaning. This explanation, developed by Kripke (1972), Kaplan (1989), and Stalnaker (1997), relies on a sharp distinction between the semantic question of what a word refers to and the metasemantic question of why a word refers to what it does. DR is a semantic claim (i.e., sentences containing names express Russellian singular propositions), and the causal-historical theory suggests a complimentary metasemantic claim (i.e., co-referential names are distinct words with different causal histories, and so there may be all manner of non-semantic differences between them). The thought is that these (non-semantic) differences can explain why uses of co-referential names can communicate different things, even though the names are semantically equivalent.

Whether such an account holds any promise of saving DR from Frege's problem is also much contested. For attempts to make the case, see Salmon (1986) and Soames (2002); for arguments against its promise, see Schiffer (1987, 2003: Chap. 2). These and other debates surrounding DR continue to be among the most vibrant in contemporary philosophy of language.

Discourse Representation Theory

The Problem of Unbound Anaphora

The most straightforward way to establish links between anaphoric pronouns and their antecedents is to translate the pronouns as variables bound by their antecedents. This approach does not work when the link crosses a sentence boundary, as in example (1).

- (1) *A man₁ met an attractive woman₂. He₁ smiled at her₂.*

It should be possible to interpret the first sentence of this discourse as soon as it is uttered, and then later on, while processing the second sentence, establish the links between the pronouns and their intended antecedents.

One possible solution is translating the indefinites by means of existential quantifiers with scopes

extending beyond the sentence level and then allowing the variables for the pronouns to be captured by these quantifiers. But this will not do: at some point the scope of a quantifier must be 'closed off,' but further on another pronoun may occur that must be linked to the same antecedent.

The bound variable approach to anaphora also fails for cases where a pronoun in the consequent of a conditional sentence is linked to an indefinite noun phrase in the antecedent of the conditional, as in example (2).

- (2) *If a man₁ meets an attractive woman₂, he₁ smiles at her₂.*

A possible approach here would be to view (2) as a combination of the noun phrases *a man* and *an attractive woman* with a structure containing the appropriate gaps for antecedents and pronouns, viz., (3). This is the approach of *quantifying-in*, taken in traditional Montague grammar (see **Montague Semantics**).

- (3) *If PRO₁ man meets PRO₂, PRO₁ smiles at PRO₂.*

This approach does not work here, however. Quantifying-in the indefinite noun phrases in (3), i.e., in a structure that has the conditional already in place, would assign the wrong scope to the indefinites with respect to the conditional operator.

Note that the meaning of (2) is approximately the same as that of (4).

- (4) *Every man who meets an attractive woman₁ smiles at her₁.*

In this case as well, quantifying-in does not allow one to generate the most likely reading where the subject of the sentence has wide scope over the embedded indefinite. Sentences with the patterns of (2) and (4) have reached the modern semantic literature through Geach (1962). Geach's discussion revolves around examples with donkeys, so these sentences became known in the literature as '*donkey sentences*.'

As has repeatedly been remarked in the literature, there are quite striking structural parallels between nominal and temporal anaphora. The past tense can be viewed as an anaphoric element in all those cases where it is not to be understood as 'sometime in the past' but as referring to some definite past time.

- (5) *John saw Mary. She crossed the street.*

In example (5), presumably the seeing takes place at some specific time in the past, and the crossing takes place immediately after the seeing. Again, we have an anaphoric link across sentence boundaries, and a traditional operator approach to tense does not seem to fit the case. Although tense is not treated in the pioneer papers on discourse representation, it is clear that the problem of temporal anaphora is a very important subproblem of the general anaphora problem that discourse representation theory sets about to solve.

Basic Ideas

Discourse representation theory as it was presented in Kamp (1981) addressed itself specifically at the problem of the previous section, although confined to nominal anaphora. The basic idea of the approach is that a natural language discourse (a sequence of sentences uttered by the same speaker) is interpreted in the context of a representation structure. The result of the processing of a piece of discourse in the context of representation structure R is a new representation structure R' ; the new structure R' can be viewed as an updated version of R .

The interpretation of indefinite noun phrases involves the introduction of '*discourse referents*' or '*reference markers*' for the entities that a piece of discourse is about. In the following, the term

'*discourse referent*' will be used. Discourse referents are essentially free variables. Thus, indefinite noun phrases are represented without using existential quantifiers. The quantification is taken care of by the larger context. It depends on this larger context whether an indefinite noun phrase gets an existential reading or not.

The life span of a discourse referent depends on the way in which it was introduced. All 'alive' referents may serve as antecedents for anaphors in subsequent discourse. Anaphoric pronouns are represented as free variables linked to appropriate antecedent variables. Definite descriptions in their simplest use are treated in a way that is similar to the treatment of anaphoric pronouns: definite noun phrases in their anaphoric use are treated like indefinite noun phrases; i.e., they are translated as free variables, but give rise to additional anaphoric links. The treatment of other, functional uses of definite noun phrases (as in *A car crashed. The driver emerged unharmed.*) is more involved.

The difference between indefinite noun phrases, on the one hand, and definite noun phrases and pronouns, on the other, is that indefinites introduce *new* variables, whereas the variables introduced by definites and pronouns are always linked to an already established context. In other words, the difference between definites (including pronouns) and indefinites is that the former refer to entities that have been introduced before, i.e., to *familiar* entities, whereas the latter do not.

Quantifier determiners, i.e., determiners of noun phrases that are neither definite nor indefinite, can bind more than one variable. Specifically, they can bind a *block* of free variables, some of which may have been introduced by indefinites. Conditional operators (*if ... then ...* constructions) can also bind blocks of free variables. Not all variables introduced by indefinites are in the scope of a quantifier or a conditional operator. Those that are not are existentially quantified over by default.

The processing of a piece of discourse is incremental. Each next sentence to be processed is dealt with in the context of a structure that results from processing the previous sentences. The processing rules decompose a sentence, replacing the various parts by *conditions* to be added to the structure. Assume one is processing discourse (6) in the context of representation structure (7) containing just one discourse referent and one condition.

- (6) *A man walked down the street. He whistled.*

- (7) (x) (*street* (x))

As was mentioned before, indefinite noun phrases give rise to new discourse referents, and definite noun

phrases are linked to existing discourse referents. The indefinite in the first sentence of (6) introduces a new discourse referent y and two conditions $man(y)$ and y *walked down the street*. The second condition can be decomposed further by introducing a fresh discourse referent in the structure, linking this discourse referent to an existing discourse referent, and replacing the definite noun phrase with the discourse referent in two new conditions. This gives three new conditions all in all: $z = x$, *street*(z) and *walked-down*(y , z). The discourse representation structure now looks like

- (8) (x, y, z) (*street*(x), *man*(y), $z = x$, *street*(z),
walked-down(y , z))

Processing the second sentence of (1) gives rise to a new link and a new condition. The final result is (9).

- (9) (x, y, z, u) (*street*(x), *man*(y), $z = x$, *street*(z),
walked-down(y , z), $u = y$, *whistled*(u))

All representation conditions in the above example are atomic. Quantified noun phrases or logical operators, such as conditionals or negations, give rise to complex conditions. The representation structure for (4) given in (10) provides an example.

- (10) $((x, y)$ (*man*(x), *woman*(y), *attractive*(y),
meet(x , y))) \Rightarrow $((), (\textit{smiles-at}$ (x , y)))

Note the appearance of an arrow \Rightarrow between components of the structure, glueing two nonatomic pieces of representation together. Note also that the right-hand component starts with an empty list $()$, to indicate that on the right-hand side no new discourse referents are introduced.

In the box format that many people are perhaps more familiar with, (10) looks like (11).

- (11)

x	y
<i>man</i> x	
<i>woman</i> y	
<i>attractive</i> y	
<i>meet</i> (x , y)	

 \Rightarrow

<i>smiles-at</i> (x , y)

Formal definitions and truth conditions for these representation structures are given in the next section.

Kamp (1981) and Kamp and Reyle (1990) spell out the rules for processing sentences in the context of a representation structure in all the required formal detail. An important feature of the rules is that they impose formal constraints on availability of discourse referents for anaphoric linking. Roughly, the set of available discourse referents consists of the discourse referents of the current structure, plus the discourse referents of structures that can be reached from the current one by a series of steps in the directions *left* (i.e., from the consequent of a pair $R \Rightarrow R'$ to the antecedent), and *up* (i.e., from a structure to an

encompassing structure). The constraints on discourse referent accessibility are used to explain the awkwardness of anaphoric links, as in (12).

- (12) *If every man_1 meets an attractive $woman_2$, he_1 smiles at her_2 .

Such data can be disputed, but space does not permit such indulgence here. Discourse referents for proper names are always available for anaphoric reference; to reflect this fact, such discourse referents are always included in the list of discourse referents of the top-level structure.

To account for deictic uses of pronouns, use is made of *anchored structures*. An anchored structure is a pair consisting of a representation structure R and a function f , where f is an *anchor* for a subset of the discourse referents of R ; i.e., f assigns appropriate individuals in a model to these discourse referents. For example, structure (7) could be anchored by mapping discourse referent x to an appropriate street. Deictic pronouns are handled by linking them to anchored discourse referents.

Essentially the same approach to natural language analysis as was proposed in Kamp (1981) is advocated in Heim (1982). Heim uses the metaphor of a filing cabinet: the established representation structure R is a file, and additions to the discourse effect a new structure R' , which is the result of changing the file in the light of the new information (see **Dynamic Semantics**).

The main program of discourse representation theory (in its generic sense) is an attempt to regard semantic interpretation as a dynamic process mapping representations plus contexts to new representations plus contexts. As Partee (1984) remarked, this shift from static semantics to dynamic semantics *cum* pragmatics means an enrichment of the enterprise of formal semantics and should therefore make it easier to establish contact with other schools of semantics and/or pragmatics. Partee's prediction was proved correct in subsequent years by the widespread use of discourse representation theory in computational linguistics and by the application of techniques of anaphora resolution from Artificial Intelligence in systems based on discourse representation theory.

Discourse representation theory has also provided new inspiration to traditional Montague grammarians, who tend to be less than satisfied with the contextual rules for analyzing discourse on the grounds that the influence of context makes it difficult to work out what contribution individual phrases make to the meaning of the whole. A suitable dynamic perspective on the process of interpretation has shown these compositionality qualms to be unfounded, and discourse representation theory has been instrumental

in bringing about this dynamic turn (see **Dynamic Semantics** for details).

Heim (1990) contains a perceptive appraisal of various alternatives to the approach of discourse representation theory (in its generic sense) to the problem of unbound anaphora.

Discourse Representation Structures (DRSs)

Formally, a discourse representation structure R consists of two parts: a finite list of *discourse referents* and a finite list of *conditions*. The discourse referents in the list are called the discourse referents of R . The conditions of a structure R may contain discourse referents that are not included in the list of discourse referents of R . Conditions can be *atoms*, *links*, or *complex conditions*. An atom is a predicate name applied to a number of discourse referents, a link is an expression $t = r$, where r is a discourse referent and t is either a proper name or a discourse referent. The clause for complex conditions uses recursion; a complex condition is a condition of the form $R \Rightarrow R'$, where R and R' are discourse representation structures.

Next, one defines truth for discourse representation structures with respect to a model. Call $M = \langle D, I \rangle$ an appropriate model for discourse representation structure R if I maps the discourse referents of R to members of D , the n -place predicate names in the atomic conditions of R to n -place relations on D , the names occurring in the link conditions of R to members of D , and (here is the recursive part of the definition) M is also appropriate for the structures in the complex conditions of R .

Let $M = \langle D, I \rangle$ be an appropriate model for structure R . An assignment in $M = \langle D, I \rangle$ is a mapping of discourse referents to elements of D . Assignment f verifies R in M if there is an extension f' of f with the following properties:

1. f' is defined for all discourse referents of R and for all discourse referents occurring in atomic or link conditions of R .
2. If $P(r_1, \dots, r_n)$ is an atomic condition of R , then $\langle f'(r_1), \dots, f'(r_n) \rangle \in I(P)$.
3. If $t = r$ is a link condition of R , and t and r are both discourse referents, then $f'(t) = f'(r)$; if t is a proper name and r a discourse referent, then $I(t) = f'(r)$.
4. If $R_1 \Rightarrow R_2$ is a complex condition of R , then every assignment for R_1 that verifies R_1 and agrees with f' on all discourse referents that are not discourse referents of R_1 also verifies R_2 .

A structure R is true in M if the empty assignment verifies R in M . These definitions can be modified to take anchors into account in the obvious way, by focusing on assignments extending a given anchor.

Clearly, the expressive power of this basic representation language is quite limited. In fact, there is an easy recipe for translating representation structures to formulae of first-order predicate logic. Assuming that discourse referents coincide with predicate logical variables, the atomic and link conditions of a representation structure are atomic formulae of predicate logic. The translation function $^\circ$, which maps representation structures to formulae of predicate logic, is defined as $R^\circ = \bigwedge C_i^\circ$, where \bigwedge indicates a finite conjunction and the C_i° are the translations of the conditions of R . The translation for conditions is in turn given by the following clauses.

- For atomic conditions: $C^\circ = C$.
- For complex conditions: $(R_1 \Rightarrow R_2)^\circ = \forall x_1 \dots \forall x_n (R_1^\circ \Rightarrow \exists y_1 \dots \exists y_m R_2^\circ)$, where x_1, \dots, x_n is the list of discourse referents of R_1 and y_1, \dots, y_m the list of discourse referents of R_2 .

It is easy to show that R is true in M under the definition given above if and only if R° is true in M for some assignment, under Tarski's definition of truth for first-order predicate logic.

A slight extension of the discourse representation language allows for the treatment of negation. Negated conditions take the form $\neg R$, where R is a discourse representation structure. Negations of atomic conditions are treated as negations of discourse representation structures containing just one atomic condition. The discourse referents of a negated structure are not available for anaphoric linking outside that structure.

The definition of satisfaction must take negated conditions into account. Here is the required extension of the definition. Assignment f verifies R in M if there is an extension f' of f with the following properties:

- 1–4. As above.
5. If $\neg R'$ is a complex condition of R , then no assignment that agrees with f' on all discourse referents that are not discourse referents of R' verifies R' .

Translation into predicate logic now must take care of negation as well. The translation clause for negated conditions runs as follows:

- $(\neg R)^\circ = \neg \exists x_1 \dots \exists x_n R^\circ$

Here x_1, \dots, x_n is the list of discourse referents of R . It is easy to see that the given translation is meaning-preserving. It is also not difficult to give a meaning-preserving translation in the other direction. This shows that the discourse representation language extended with negation has precisely the same expressive power as first-order predicate logic.

Extensions: Tense and Plurals

Partee (1984) gave a survey of proposals to extend discourse representation theory with discourse referents for times and events to exploit the parallels between nominal and temporal anaphora. In example (5) from section 1, where first reference is made to a seeing event in the past and then to an event of crossing the street that takes place immediately after the seeing event, an anchoring mechanism can be used to link the seeing event to the appropriate time, and an anaphoric link between events can constrain the time of the crossing event in the appropriate way. Also, the dynamic effect of shifting the reference time can be incorporated by using a designated discourse referent for the reference time and specifying that this discourse referent be updated as a side effect of the processing of sentences denoting events.

Next, there are examples where a reference is picked up to an indefinite time in the past.

- (13) *Mary arrived during the day. She let herself into the house.*

In example (13), the arrival takes place at some indefinite time on a specific day (presumably anchored) in the past. The event of Mary's entering the house is then linked to the time of arrival. Again, all that is needed is the introduction of an event discourse referent for the arrival event and an appropriate linking of this event discourse referent to the reference time discourse referent: the reference time discourse referent starts pointing at a time interval just after the time of arrival. The processing of the next sentence introduces an event that is constrained to be included in the reference time interval and has again as a side effect that the reference time discourse referent is shifted to refer to a time interval just after the house-entering event.

Sentence (14) provides an example of quantification over times.

- (14) *When Bill called, Mary was always out.*

The example gives rise to a complex representation of the form $R \Rightarrow R'$, with an event discourse referent and a reference time discourse referent introduced in the left-hand structure, and a state discourse referent of the right-hand structure, with the state constrained to include the reference time interval.

An operator account of tenses and temporal adverbs has the awkwardness that the tense operator is redundant if a temporal adverb is present, as in (15), but not otherwise. Also, assigning the correct scopes to these operators poses problems.

- (15) *Bill called last Friday around noon.*

In the discourse representation approach, where tenses translate into event or state variables linked to an appropriate reference time, temporal operators are simply translated as predications on the event discourse referent, and the awkwardness vanishes. See Kamp and Rohrer (1983) and Partee (1984), plus the references cited therein, for details.

As for the incorporation of the singular versus plural distinction, an obvious first move in any attempt to accommodate plural anaphoric pronouns is to make a distinction between singular and plural discourse referents. Singular pronouns are linked to singular discourse referents, and plural pronouns are linked to plural discourse referents. Plural indefinite noun phrases (*some women, three men*) introduce plural discourse referents, but it turns out that many other introduction mechanisms must be postulated to obtain a reasonable coverage of plural anaphoric possibilities.

Plural discourse referents may result from *summation* of singular discourse referents. This is to account for uses of *they* that pick up a reference to a set of individuals that have been introduced one by one. Next, plural individuals may be the result of *abstraction* from complex conditions. Consider example (16).

- (16) *John bought every book Mary had mentioned. He started reading them straight away.*

Obviously, *them* refers to the set of all books mentioned by Mary. No plural discourse referent is introduced by the first sentence, so the only way to make one available is by calling it into being through abstraction.

So-called *dependent plurals* should be handled differently again, because here the plurality seems closely linked to syntax. Sentence (17) provides an example.

- (17) *All my friends have children.*

It is clear that (17) is still true if each of my friends has exactly one child. Dependent plurals call for a kind of in-between discourse referent that is neutral between singular and plural. The chapter on plurals in Kamp and Reyle (1990) gives a very detailed account of these and related matters. **Plurality** provides further information on general issues of the interpretation of plurals.

Incorporating Generalized Quantifiers

Extending discourse representation theory with nonstandard quantifiers, and then getting the truth conditions right, is not completely straightforward.

- (18) *Most farmers who own a donkey beat it.*

Applying a routine strategy for building a representation structure for example (18), one arrives at

structure (19), where $R \Rightarrow_m \Rightarrow R'$ is true if most verifying assignments for R are verifying assignments for R' .

$$(19) ((x, y)(\text{farmer}(x), \text{donkey}(y), \text{own}(x, y))) \Rightarrow_m \Rightarrow ((\))(\text{beat}(x, y)))$$

This analysis does give the wrong truth conditions, because it quantifies over farmer–donkey pairs instead of individual farmers. In a situation where there are five kind farmers who each own 1 donkey and treat it well, and one cruel, rich farmer who beats each of his 10 donkeys, the analysis makes sentence (18) true, though intuitively it should be false in this situation.

The remedy (proposed in Kamp and Reyle, 1990) involves a complication in the notation. Generalized quantifiers are introduced explicitly in the representation structures. The revised representation for (18) is (20).

$$(20) ((x, y)(\text{farmer}(x), \text{donkey}(y), \text{own}(x, y))) \Rightarrow_x^{\text{most}} \Rightarrow ((\))(\text{beat}(x, y)))$$

At the place of *most* in (20) one could in principle have any generalized quantifier (see **Quantifiers: Semantics**). In other words, for every binary generalized quantifier Q and every pair of representation structures R, R' , the following is a complex condition: $R \Rightarrow_v^Q \Rightarrow R'$. The truth conditions are modified to reflect what is expressed by the quantifier Q . Generalized quantifiers express relations between sets, so $R \Rightarrow_x^Q \Rightarrow R'$ is true in case the two sets are in the appropriate quantifier relation. The truth conditions must pick out the two relevant sets. Here is the new part of the definition. Assignment f verifies R in M if there is an extension f' of f with the following properties:

1–5. As above.

6. If $R_1 \Rightarrow_v^Q \Rightarrow R_2$ is a complex condition of R , then f' verifies this condition if the sets B and C are in the quantifier relation denoted by Q , where $B = \{b \mid f' \text{ has an extension } g \text{ with } g(v) = b, \text{ which verifies } R_1 \text{ in } M\}$ and $C = \{c \mid f' \text{ has an extension } h \text{ with } h(v) = c, \text{ which verifies } R_2 \text{ in } M\}$.

It is left to the reader to check that this gets the truth conditions for (18) correct.

The following representation of (18) brings the incorporation of generalized quantifiers more in line with standard logical notation:

Discourse Structures and Partial Models

There is more than an occasional hint in the original papers of Kamp and Heim that discourse representation structures are closely connected to *partial* models. If the suggestion is not that these representation structures are themselves partial models, it is at least that they are intended to be interpreted with respect to partial models. That the structures are themselves partial models cannot be right: complex conditions are *constraints* on models rather than model components. They specify general properties that a model must satisfy the condition. Interpretation of discourse representation structures in partial models has never really been worked out. The truth definitions for representation structures, e.g., in Heim (1982), Kamp (1981), Kamp and Reyle (1990), define satisfaction in classical (i.e., ‘complete’) models.

Because the representation structures contain identity links and negated identity links, evaluation in partial models where not only the predicates used to translate the vocabulary of the fragment, but also the identity predicate receives a partial interpretation, is feasible. Interestingly, this sheds light on some puzzling aspects of identity statements. Current studies of partial model theory interpret identity as a total predicate (see Langholm, 1988). Partializing identity leads to a more radical form of partiality; it has the effect that the objects in the model are not proper individuals but rather proto-individuals that can still fuse into the same individual after some more information acquisition about the identity relation. Technically, this form of radical partiality can be implemented by evaluating discourse representation structures with respect to models where the identity relation is a partial relation.

The formal development of a theory of partial identity involves an interpretation of identity as a pair $\langle I^+, I^- \rangle$, with I^+ an equivalence relation that denotes the positive extension of identity, and I^- an anti-equivalence relation, that is to say, a relation that is irreflexive, symmetric, and anti-transitive, i.e., satisfying the requirement that if I^-xy , then it holds for all z that I^-xz or I^-zy .

The assumption that proto-individuals rather than regular individuals populate the partial models is attractive from the point of view of knowledge representation: often human beings have only partial information about identities. Famous paradoxes and puzzles are based on this fact. One example is Frege’s morning star, evening star paradox; see the article **Coreference: Identity and Similarity**. Another is Saul Kripke’s Pierre puzzle. Pierre is a Frenchman who has read about a famous and wonderful city he knows as *Londres*, and because of his reading he thinks that

Londres is pretty. Later on, he is abducted and forced to work in a slum in a city that, as he learns, is called *London*, and this new experience leads him to conclude that *London* is ugly. The important point to note is that as long as all this information is processed with respect to a partial model where *London* and *Londres* name different proto-individuals, Pierre's beliefs are not incoherent. They only become incoherent once it is discovered that *London* and *Londres* are identical, i.e., once Pierre acquires additional information about the extension of the identity relation. From outside, from a situation where *London* and *Londres* are anchored to the same individual, the belief may seem incoherent as well, but the point is that Pierre does not have full information about the nature of this anchor. The example is discussed in the context of discourse representation theory in Asher (1986), but the solution proposed there is still phrased in terms of classical models.

Reasoning with DRSs

The plausibility of using Discourse Representation Structures to model belief and other propositional attitudes is closely connected with the existence of cognitively plausible inference systems for DRSs. Proof theories for DRSs are given in Saurer (1993), Kamp and Reyle (1996), and Van Eijck (1999). The calculus of Van Eijck (1999) is perhaps the simplest of these, and we present it here.

We switch to the version of DRT where DRS negation is primitive and $D_1 \Rightarrow D_2$ is defined in terms of negation. The precise definition is given below. A slight modification of the DRS definition is to make a distinction between the *fixed* discourse referents and the *introduced* discourse referents of a DRS (first proposed in Visser 1994). This allows for a natural definition of DRT consequence. If a DRS is inferred, its fixed discourse referents are supposed to be supplied by the premises of the inference. They are 'fixed by the context of the inference,' so to speak.

Thus, we view a DRS as a triplet consisting of a set of fixed referents F , a set of introduced referents I , and a set of conditions $C_1 \dots C_n$ constrained by the requirement that the free variables in C_i must be among $F \cup I$. Concretely, the syntax of DRT looks like this (equality statements left out for simplicity of exposition):

Definition 1 (DRT)

$$\begin{aligned} t &::= c \mid v \\ C &::= T \mid Pt_1 \dots t_n \mid \neg D \\ D &::= \frac{v_1 \dots v_n \quad v_{n+1} \dots v_m}{C_1 \dots C_k} \end{aligned}$$

We will use \perp as an abbreviation of $\neg \top$. The (active) discourse referents of a term t or condition C or DRS D are given by:

$$\begin{aligned} M(v) &:= \{v\}, M(c) := \emptyset, M(T) := \emptyset, M(Pt_1 \dots t_n) := \cup_i M(t_i), \\ M\left(\frac{F \quad I}{C}\right) &:= F \cup I, M\left(\neg \frac{F \quad I}{C}\right) := F \end{aligned}$$

Conditions on the formation rule for a DRS

$$\frac{v_1 \dots v_n \quad v_{n+1} \dots v_m}{C_1 \dots C_k}$$

1. $\{v_1 \dots v_n\} \cap \{v_{n+1} \dots v_m\} = \emptyset$.
2. $\cup_i M(C_i) \subseteq \{v_1 \dots v_m\}$

We define the condition

$$\frac{F \quad I}{C_1 \dots C_n} \Rightarrow D$$

as

$$\neg \frac{F \quad I}{C_1 \dots C_n \neg D}$$

Here is a semantics for DRT in terms of partial assignments, following the original set-up in Kamp (1981).

Definition 2 (Semantics of DRT)

$$\begin{aligned} \mathcal{M}, f &\models T && \text{always} \\ \mathcal{M}, f &\models Pt_1 \dots t_n && \text{iff } \langle [t_1]_f^{\mathcal{M}}, \dots, [t_n]_f^{\mathcal{M}} \rangle \in P^{\mathcal{M}} \\ \mathcal{M}, f &\models \neg D && \text{iff there is no } g \text{ with } \mathcal{M}, f, g \models D \end{aligned}$$

$$\mathcal{M}, f, g \models \frac{F \quad I}{C_1 \dots C_n} \text{ iff } \begin{aligned} &f : F \rightarrow \text{dom}(\mathcal{M}), \\ &g : F \cup I \rightarrow \text{dom}(\mathcal{M}), f = g \upharpoonright F, \\ &M, g \models C_1, \dots, M, g \models C_n. \end{aligned}$$

Here $g \upharpoonright F$ denotes the restriction of function g to the set F . The following definition of DRT consequence makes essential use of the distinction between fixed and introduced discourse referents.

Definition 3 (DRT Consequence)

$$\frac{F \quad I}{C_1 \dots C_n} \models \frac{F \cup I \quad I}{C_{n+1} \dots C_m}$$

$$\text{iff for all } \mathcal{M}, f, g \text{ with } \mathcal{M}, f, g \models \frac{F \quad I}{C_1 \dots C_n}$$

$$\text{there is an } h \text{ with } \mathcal{M}, g, h \models \frac{F \cup I \quad I'}{C_{n+1} \dots C_m}$$

A DRT calculus is given in Figure 1 (lists $C_1 \dots C_k$, abbreviated as C). The calculus uses substitution in constraints and DRSs. This notion is defined by

Test axiom	$\frac{\boxed{\begin{array}{ c c } \hline F & \phi \\ \hline C \\ \hline \end{array}}}{\Rightarrow} \boxed{\begin{array}{ c c } \hline F & \phi \\ \hline C \\ \hline \end{array}} \quad M(C) \subseteq F$
Transitivity	$\frac{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & \phi \\ \hline C_1 \\ \hline \end{array}} \quad \boxed{\begin{array}{ c c } \hline F & \phi \\ \hline C_1 \\ \hline \end{array}} \Rightarrow \boxed{\begin{array}{ c c } \hline F & I \\ \hline C_2 \\ \hline \end{array}}}{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & I \\ \hline C_2 \\ \hline \end{array}}}$
Marker intro	$\frac{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & I \\ \hline [t/v] C \\ \hline \end{array}} \quad v \notin F}{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & \{v\} \cup I \\ \hline C \\ \hline \end{array}}}$
Marker shift	$\frac{\boxed{\begin{array}{ c c } \hline F & I \\ \hline C \\ \hline \end{array}} \Rightarrow D}{\boxed{\begin{array}{ c c } \hline F - I_0 & I_0 \cup I \\ \hline C \\ \hline \end{array}} \Rightarrow D}$
Sequencing-l	$\frac{\boxed{\begin{array}{ c c } \hline F & I \\ \hline C \\ \hline \end{array}} \Rightarrow D \quad \boxed{\begin{array}{ c c } \hline F & I \\ \hline C_0 \cup C \\ \hline \end{array}} \Rightarrow D \quad M(C_0) \subseteq F \cup I}{\boxed{\begin{array}{ c c } \hline F & I \\ \hline C_0 \cup C \\ \hline \end{array}} \Rightarrow D}$
Sequencing-r	$\frac{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & I_1 \\ \hline C_1 \\ \hline \end{array}} \quad D \Rightarrow \boxed{\begin{array}{ c c } \hline F & I_2 \\ \hline C_2 \\ \hline \end{array}} \quad I_1 \cap I_2 = \phi}{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & I_1 \cup I_2 \\ \hline C_1 \cup C_2 \\ \hline \end{array}}}$
Neg	$\frac{\boxed{\begin{array}{ c c } \hline F & I \\ \hline C \\ \hline \end{array}} \Rightarrow D \quad \boxed{\begin{array}{ c c } \hline F & I \\ \hline C \cup \{ \neg D \} \\ \hline \end{array}} \Rightarrow \perp \quad \boxed{\begin{array}{ c c } \hline F & I_1 \cup I_2 \\ \hline C_1 \cup C_2 \\ \hline \end{array}} \Rightarrow \perp \quad M(C_1) \cap I_2 = \phi}{\boxed{\begin{array}{ c c } \hline F & I_1 \\ \hline C_1 \\ \hline \end{array}} \Rightarrow \neg \boxed{\begin{array}{ c c } \hline F \cup I_1 & \phi \\ \hline F \cup I_1 & I_2 \\ \hline C_2 \\ \hline \end{array}}}$
Double-neg	$\frac{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & \phi \\ \hline \neg \neg F & I \\ \hline C \\ \hline \end{array}} \quad \boxed{\begin{array}{ c c } \hline F & I_1 \\ \hline C_1 \cup \{ \neg \neg F \cup I_1 & \phi \\ \hline \neg \neg F \cup I_1 & I_2 \\ \hline C_2 \\ \hline \end{array}} \Rightarrow \perp}{D \Rightarrow \boxed{\begin{array}{ c c } \hline F & I \\ \hline C \\ \hline \end{array}} \Rightarrow \perp}$

Figure 1 The calculus for DRT.

$$\begin{aligned}
[t/v]I &:= I \\
[t/v]Pt_1 \cdots t_n &:= P[t/v]t_1 \cdots [t/v]t_n \\
[t/v]\neg D &:= \neg[t/v]D \\
[t/v]\frac{\boxed{\begin{array}{|c|c|} \hline F & I \\ \hline C_1 \cdots C_n \\ \hline \end{array}}}{\vdash} &:= \frac{\boxed{\begin{array}{|c|c|} \hline F & I \\ \hline [t/v]C_1 \cdots [t/v]C_n \\ \hline \end{array}}}{\vdash}
\end{aligned}$$

Of course, when a substitution $[t/v]$ is mentioned in a rule, it is assumed that t is free for v in D . It is also assumed that all DRSs mentioned in the rules satisfy the syntactic well-formedness conditions for DRSs.

Theorem 4

The calculus for DRT is sound.

Proof Induction on the basis that the test axiom is sound and that the rules preserve soundness. Here is one example soundness check, for the rule of marker introduction. Assume $\mathcal{M}, f, g \models D$. Then by the soundness of the premise, there is an h with

$$\mathcal{M}, g, h \models \boxed{\begin{array}{|c|c|} \hline F & I \\ \hline [t/v] C \\ \hline \end{array}}$$

Thus, $\mathcal{M}, h \models [t/v] C$. Since $v \notin F$, h' given by $h'(v) = \llbracket t \rrbracket_b^{\mathcal{M}}$, and $h'(w) = h(w)$ for all $w \neq v$ for which h is defined extends g . By (an appropriate DRT version of) the substitution lemma,

$$\mathcal{M}, g, h' \models \boxed{\begin{array}{|c|c|} \hline F & \{v\} \cup I \\ \hline C \\ \hline \end{array}}$$

This proves

$$D \models \boxed{\begin{array}{|c|c|} \hline F & \{v\} \cup I \\ \hline C \\ \hline \end{array}}$$

Theorem 5

The calculus for DRT is complete.

For the proof of this, we refer to Van Eijck (1999), where the proof system for DRT is related to a proof

system for dynamic predicate logic (Groenendijk and Stokhof, 1991).

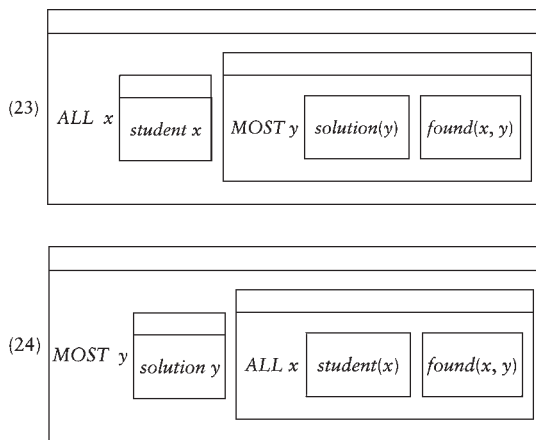

The Treatment of Ambiguities

If an expression of a formal language is viewed as a tree, a partial specification of how the expression is built up from its components can be given by means of a description of constraints on syntax tree construction.

This is the approach to the treatment of ambiguities taken in Underspecified DRT (UDRT) (Reyle, 1993). In UDRT, a DRS is viewed as a tree, and an UDRS is viewed as a set of constraints on tree formation.

(22) *All students found most solutions.*

To represent the scope ambiguity between the two quantifiers in (22), one needs a representation that is ‘in between’ the following two DRSs:

The UDRT solution is to take the DRSs apart, to label the parts, and to define an UDRS as a set of labeled DRS parts plus a list of constraints between labels. An UDRS for the example case has a top node \top labeled l_0 , nodes

$ALL\ x$

$student(x)$

, $MOST\ y$

$solution(y)$

,

$found(x, y)$

labeled l_1, l_2, l_3 , respectively, and constraints $l_0 \leq l_1, l_0 \leq l_2, l_1 \leq l_3, l_2 \leq l_3$. Full disambiguation can be achieved by adding a further constraint. Adding the constraint $l_1 \leq l_2$ disambiguates the UDRS to (23), while adding the constraint $l_2 \leq l_1$ results in disambiguation to (24).

Donkey Sentences

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

The problem of ‘donkey sentences’ occupies a prominent place in the logical analysis of natural language sentences. The purpose of logical analysis of sentences is to assign them a structure suitable for logical calculus – that is, the formal derivation of entailments. Some variety of the language of predicate calculus (LPC) is normally used for logical translations.

In LPC, a term in a proposition that has a truth value must either be an expression referring to an individual (or a set of individuals) that actually exists or be a bound variable. Modern predicate calculus is essentially extensional: truth values are computed on the presumption that term referents actually exist, so that it allows in all cases for substitution of coextensional constituents *salva veritate*. Intensional or virtual objects – objects that have merely been thought up but that lack actual existence – have no place in modern logic, just as they have no place in Quine’s ‘desert landscape’ ontology, which has gained currency in large sections of Anglo-Saxon philosophy. That being so, modern logic has no choice but to posit that any argument term of a predicate in a proposition that has a truth value either refers to an actually existing object or is a bound variable ranging over such objects.

Since in natural language one often encounters expressions that have the appearance of being referring argument terms but in actual fact fail to refer – such as the famous sentence in Bertrand Russell’s (1905) article *The present king of France is bald* – Quine (1960) started a “program of elimination of particulars” aimed at reformulating natural language sentences exclusively in terms of the quantificational language of modern predicate calculus, without any referring terms. Thus, for Quine and large sections of the logical community, LPC bans all definite terms and allows only for variables in argument positions.

This, however, will not do for natural language, which has sentences that express purely extensional propositions and yet contain terms that neither refer to an actually existing object nor allow for an analysis as bound variable. These are the so-called donkey sentences. The fact that natural language resists analysis in terms of LPC constitutes the problem posed by the donkey sentences.

The currency of the term ‘donkey sentences’ originates with the British philosopher Peter Geach, whose

discussion of certain sentences, all about donkeys, awakened the interest of modern logicians (Geach, 1962). Geach did not mention – apart from a token reference (1962: 116) to “another sort of medieval example” – that he took his cue from Walter Burleigh (c.1275–after 1344), who introduced donkey sentences in the context of supposition theory, the medieval equivalent of reference theory. In Burleigh (1988: 92), written around 1328, one finds this example:

- (1) *Omnis homo habens asinum videt illum.*
(‘Every man owning a donkey sees it.’)

Burleigh’s problem had nothing to do with LPC, which did not yet exist. His problem was of a different nature. Having noticed that there exist what we now call bound variable pronouns, as in (2), and having stated that these may never take as antecedent a constituent of the same clause (*propositio categorica*), he presented (1) as an apparent counterexample, since the pronoun *illum* takes as antecedent *asinum*, which stands under the same verb (*videt*) and is thus in the same clause.

- (2) All boys expected that the dog would bite *them*.

His answer was that the antecedent of *illum*, i.e., *asinum*, is not a main constituent of the same clause but a constituent of a subordinate predication, i.e., *habens asinum* (‘owning a donkey’).

Geach (1962) discussed the same problem: how to account for the antecedent relation when the antecedent occurs in a relative clause contained in a complex predicate. It stands to reason, he said (1962: 117), to treat *man who owns a donkey* in the sentences (3a) and (3b), which he considered contradictories, as a complex predicate “replaceable by the single word ‘donkey-owner’.” But if we did that, (3a) and (3b) “become unintelligible ... because ‘it’ is deprived of an antecedent”:

- (3a) Any man who owns a donkey beats it.
- (3b) Some man who owns a donkey does not beat it.

A solution could conceivably be found in rewording these sentences as (4a) and (4b) (1962: 117):

- (4a) Any man who owns a donkey, owns a donkey and beats it.
- (4b) Some man who owns a donkey owns a donkey and does not beat it.

Yet, he says, whereas (3a) and (3b) are contradictories, at least according to native speakers’ intuitions, (4a) and (4b) are not (1962: 118):

[F]or both would be true if each donkey-owner had two donkeys and beat only one of them. Medieval logicians would apparently have accepted the alleged equivalences; for they argued that a pair such as [(3a)] and [(3b)] could both be true... and were therefore not contradictories. But plainly [(3a)] and [(3b)], as they would normally be understood, are in fact contradictories; in the case supposed, [(3b)] would be true and [(3a)] false.

The “medieval logicians” Geach argues against are in fact Walter Burleigh, who added the following comment to his discussion of (1), thereby denying that (3a) and (3b) are contradictories (1988: 92–93; translation mine):

It follows that the following are compatible: ‘Every man owning a donkey sees it’ and ‘Some man owning a donkey does not see it’. For assuming that every man owns two donkeys, one of which he sees and one of which he does not see, then it is not only true to say ‘Every man owning a donkey sees it’, but also to say ‘Some man owning a donkey does not see it’. In the same way, suppose that every man who has a son also has two sons, and that he loves the one but hates the other, then both the following are true: ‘Every man who has a son loves him’ and ‘Some man who has a son does not love him’.

Geach’s own solution was to analyze a relative clause within a predicate as an implication under universal, and a conjunction under existential quantification, as in (5).

- (5a) Any man, if he owns a donkey, beats it.
- (5b) Some man owns a donkey and he does not beat it.

This “is quite unforced and does give us a pair of contradictories, as it ought” (Geach, 1988: 92–93). Yet Geach apparently failed to realize that (5a) does not translate into modern predicate logic. Its translation would have to be something like (6), which contains the free variable y in $\text{Beat}(x, y)$

- (6) $\forall x[\text{Man}(x) \rightarrow [\exists y[\text{Donkey}(y) \wedge \text{Own}(x, y)] \rightarrow \text{Beat}(x, y)]]$

Had he realized that, he would have hit on the donkey sentences problem as it lives in modern formal semantics.

Geach strengthened his putative solution by arguing (1972: 115–127) that a sentence like (7) should not be translated as a conjunction of two propositions – as $A \wedge B$ – but rather as a single quantified proposition with *it* translated as a bound variable, as in (8).

- (7) Smith owns a donkey and he beats it.
- (8) $\exists x[\text{Donkey}(x) \wedge \text{Own}(\text{Smith}, x) \wedge \text{Beat}(\text{Smith}, x)]$

His argument amounts to saying that $A \wedge B$ and $A \wedge \neg B$ cannot be true at the same time, whereas (7)

and (9) can. All it takes is for Smith to own two donkeys, only one of which he beats.

- (9) Smith owns a donkey and he does not beat it.

Therefore, Geach argues, the logical translation (8) is correct, since it is compatible with (10), which simply posits a second ass, owned by Smith but not beaten by him

- (10) $\exists x[\text{Donkey}(x) \wedge \text{Own}(\text{Smith}, x) \wedge \neg \text{Beat}(\text{Smith}, x)]$

This analysis, however, cannot be correct, as pointed out in Seuren (2001: 316–318), since it lacks generality in view of cases like (11).

- (11a) Smith must own a donkey, and he may beat it.
- (11b) I believe that Smith owns a donkey, and I fear that he beats it.
- (11c) This made Smith own a donkey and kept him from beating it.

No analysis of the type shown in (8) or (10) is applicable here, since they either require large scope for *a donkey*, which is contrary to what these sentences mean, or have to place the second operator (*may, fear, keep*) in the scope of the first (*must, believe, make*), which again is not what these sentences mean. Geach’s analysis thus comes to nothing.

All this, however, is still beating about the bush. The real problem shows up in (12):

- (12a) Every farmer who owns a donkey feeds it.
- (12b) If Smith owns a donkey, he feeds it.
- (12c) Either Smith does not own a donkey or he feeds it.

In the standard logical analysis of *if* and *or*, they come out as true if Smith owns no donkey. But then *it* cannot be translated as a referring expression (the donkey), as it lacks a referent. It should therefore be translatable as a bound variable. But that, too, turns out to be impossible. Universal quantification, proposed by Quine (1960: 139) and many others as a solution, again falls foul of possible intervening operators, as in (13) (see Seuren, 1998).

- (13a) If Smith wants to own a donkey he must promise to feed it.
- (13b) Either Smith no longer owns a donkey or he still feeds it.

There thus seems to be a hard core of sentences resisting translation into LPC. They contain definite expressions, preferably pronouns, that are neither referring expressions nor bound variables.

Also, these pronouns behave like referring expressions anaphorically linked to an antecedent, and not like bound variable pronouns. The former allow for substitution by a lexical noun phrase (‘epithet anaphora’); the latter do not. Thus, *it* in (14a), (14b),

and (14c) can be replaced by, for example, *the animal*, without much change in meaning, but *it* in (14d), which represents a bound variable, does not allow for such substitution.

- (14a) Smith owns a donkey and he feeds it/the animal.
- (14b) If Smith owns a donkey he feeds it/the animal.
- (14c) Either Smith does not own a donkey or he feeds it/the animal.
- (14d) Every donkey owned by Smith expects that he will feed it/*the animal.

Donkey pronouns, therefore, behave like referring expressions even though they are not allowed to do so under the statutes of current logic. Kamp and Reyle (1993) recognized the fundamental nature of this problem and proposed a radical departure from standard notions and techniques of semantic interpretation. They defended an analysis whereby the donkey pronouns and other definite expressions do not refer directly to entities in the world at hand but instead denote mental representations of possible real-world entities. In this theory, known as *Discourse Representation Theory*, the mechanism of reference is mediated by a cognitive system of mental representations whose relation to any actual world is a matter of independent concern. This halfway station of mental representations creates some extra room for a semantic account of donkey sentences. Even so, however, standard logical analyses are inadequate for natural language. What logic will do better justice to the facts of language is still an open question. Groenendijk and Stokhof (1991) was an attempt at answering that question.

Dthat

D Braun, University of Rochester, Rochester, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The expression *dthat* (pronounced as a single syllable) was introduced by David Kaplan (1978, 1989b) as a formal surrogate for the English demonstrative *that*. On Kaplan's theory of demonstratives, an utterance of the English demonstrative *that* is typically accompanied by a demonstration that presents an object, namely the demonstratum of the context. The demonstratum is the referent of the demonstrative in the context. The structure of *dthat*-terms reflects this theory of demonstratives. Each *dthat*-term has the form *dthat[α]*, where α is a singular term. Such a term may be used to represent an English demonstrative *cum* demonstration. When so

used, the expression *dthat* serves as a formal surrogate for the demonstrative, while α takes the form of a definite description that serves as a formal surrogate for the demonstration and fixes the reference of *dthat* in every context. In Kaplan's formal possible worlds semantics, the extension of a definite description α , with respect to a context, world, and time, is an individual. The extension of *dthat[α]* with respect to a context, world, and time is the extension of α with respect to the world and time of the context. Thus, *dthat*-terms are rigid designators with respect to a context: Given a context, the extension of a *dthat*-term is the same with respect to all worlds and times. In this respect, *dthat*-terms are like the indexical first-person pronoun *I*, whose extension, given a context, is the same individual (namely the agent of the context) with respect to all worlds and times.

Although Kaplan (1989b) presents his formal semantics in a possible worlds format, he prefers a semantics that uses Russellian structured propositions – propositions whose constituents include individuals, properties, and relations. On such a semantics, the Russellian content of a predicate, with respect to a context, is a property or relation; the content of *I*, with respect to a context, is the agent of the context; and the content of a definite description, with respect to a context, is a complex entity containing the content of the definite description's predicate and the higher-order property or relation expressed by 'the.' Kaplan's (1989b) informal remarks about *dthat* allow for two quite different interpretations of its Russellian semantics (as pointed out in Kaplan, 1989a). On the first interpretation, the Russellian content of a *dthat*-term, in a context, is an individual, namely the referent of α in that context. Kaplan (1989a) calls this the "demonstrative surrogate" interpretation of *dthat*-terms and says that, on this interpretation, the expression *dthat* standing alone is a singular term. But this semantics does not fit well with the syntax that Kaplan (1989b) ascribes to *dthat* in his formal system, where *dthat* appears to be an operator or functional expression. On the second interpretation, the content of a *dthat*-term is a complex entity that contains the content of the

definite description α together with a higher-order content for *dthat*. On this interpretation, *dthat* is a functional expression that rigidifies the attached definite description; it is similar in some respects to the expression *actually* in *the x: actually Ex*. Most theorists who use *dthat*-terms specify that a complete *dthat*-term, *dthat*[α], is a singular term whose content, in a context, is the referent of α in the context.

Dynamic Semantics

J Groenendijk and M Stokhof, Universiteit van Amsterdam, Amsterdam, The Netherlands

Information and Information Change

Dynamic semantics is a branch of formal semantics that uses dynamic logic. Dynamic logic was originally developed for the logical analysis of so-called declarative programming languages. The basic idea is that a program can be semantically interpreted as a transition relation between machine states. Two states s and t are related by a program π if, when π is executed in an input state s , t is a possible output state. For example, if the current value of x is 4, the effect of executing the assignment $x := x + 1$ will be that the new value of x is 5. A program is interpreted in terms of the change that it brings about. (Note that for a deterministic program, like the example just given, there is just one possible output state, for a given input state. But if the program threw a die, there would be several possible outputs.)

In standard logical semantics, (indicative) sentences are interpreted in terms of their truth conditions. And substantential expressions are interpreted in terms of their contribution to the truth conditional content of the sentences in which they occur. The truth conditional content of a sentence corresponds to the information it provides about the world. Dynamic semantics takes a different view on meaning. The static notion of information content is replaced by a dynamic notion of information change. The meaning of a sentence is the change in information that it brings about: meaning is 'information change potential.'

Clearly, for a program, a static interpretation in terms of truth conditions makes little sense (as could be argued for imperative or interrogative sentences in natural language). But it is less obvious what the advantages of a dynamic semantics for indicative sentences would be. At first sight, it seems that a static semantics in terms of information content also already makes it possible to give a general characterization of information change potential: 'Add the

information content of the sentence to the information about the world that is already available.'

One general type of argument in favor of a dynamic approach is that, even when we restrict ourselves to purely informative language use, there is more to meaning than can be captured in the notion of meaning as truth conditional content. A standard example (due to Barbara Partee) is the contrast between the following two sequences of sentences:

- (1) I dropped ten marbles and found all of them, except for one. It is probably under the sofa.
- (2) I dropped ten marbles and found only nine of them. ??It is probably under the sofa.

The first sentences in (1) and (2) are truth conditionally equivalent: they provide the same information about the world. Hence, if meaning is identified with truth conditional content, they have the same meaning. However, one may observe that whereas the continuation with the second sentence in (1) is completely unproblematic, the same continuation in (2) is not equally felicitous. The conclusion must be that the two opening sentences differ in meaning; hence, meaning cannot be equated with truth conditional content.

From the viewpoint of dynamic semantics, the two opening sentences in (1) and (2) differ in the way they change information, even though the information they provide about the world is the same. Unlike the opening sentence in (2), the opening sentence in (1) also creates an informational context that licenses the pronoun 'it' in the second sentence.

The notion of context is already important in standard semantics, in the sense that sentences are interpreted relative to a context of utterance, which may include several parameters, such as the time of utterance, etc. So, interpretation depends on context, or on the information available to the speech participants. What dynamic interpretation adds to this is the insight that the process of interpretation also brings about a change of the context, viz., in the information of the speech participants. Both context dependency and the creation of context in speech situations are taken into account.

One of the things this change of perspective brings is that attention shifts from isolated sentences to discourse, or text. It makes it possible to study and describe semantic phenomena that cross the border of a single sentence. As illustrated by the example given above, anaphoric relations across sentences are one such phenomenon.

Discourse Representation Theory and File Change Semantics

Dynamic semantics is not the only logical semantical theory that deals with the incremental interpretation

of discourse, and it was not the first one, either. Whereas the logical roots of dynamic semantics lie in dynamic logic and the semantics of programming languages, its linguistic roots are discourse representation theory and file change semantics.

In discourse representation theory, the interpretation of a discourse – a sequence of sentences – takes the form of an incremental construction of a discourse representation structure. In file change semantics, it is not a single structure that is built, but a system of so-called file cards. The two main elements of discourse representation structures and file card systems are discourse referents and conditions. The discourse referents behave like logical variables, and the conditions are open formulae containing these variables, thereby putting constraints on the possible values of these variables. Discourse referents are introduced by certain noun phrases, in particular indefinites, and correspond to 'individuals talked about' by the discourse. In file change semantics the introduction of a new discourse referent means adding a file card to the system. The conditions are written on the file cards, and can contain information that is spread over several cards, thereby linking them to each other. In discourse representation theory the conditions can be atomic formulae, or more complex structures that include other discourse representation structures.

The discourse referents also function as possible referents for anaphoric expressions. Anaphoric expressions have to be linked to an accessible discourse referent in the discourse representation structure or file card system as it has been constructed at that point. For example, in discourse (1) above, the phrase 'except for one' in the first sentence will have introduced a discourse referent to which the pronoun 'it' in the second sentence can be linked. In discourse (2) the first sentence does not introduce a suitable discourse referent to link 'it' to. So, discourse representation theory and file change semantics can account for the difference in acceptability of the two discourses.

The incremental construction of discourse representation structures is the first step in the interpretation process of a discourse. It clearly has a dynamic nature. Interpreting a sentence may depend on the nature of the structure created by previous sentences, and will result in a change of structure. The second step in the interpretation process of a discourse is more traditional. It consists in a semantic evaluation of the one resulting discourse representation structure relative to a standard logical model. A structure is true in a model if objects from the domain of the model can be assigned to the discourse referents in such a way that all the conditions in the structure are satisfied.

So, although the discourse representation structures are constructed dynamically, their semantic interpretation, and hence, indirectly, the semantic interpretation of the discourses they represent, are interpreted in terms of ‘static’ truth conditional content.

In our discussion of the discourses (1) and (2), we saw that the opening sentences have the same truth conditions. This will also hold for the discourse representation structures they give rise to. We concluded above that since the two discourses as a whole show different semantic behavior, the opening sentences must differ in meaning, and that hence the meaning of sentences cannot be equated with their truth conditions. Discourse representation theory accounts for the difference in meaning, but not in terms of a difference in information *content*, but in terms of a difference in the *representation* of information. The intermediate representation level thus becomes an essential ingredient of the theory of interpretation of natural language.

Dynamic semantics, in particular dynamic predicate logic, was invented to show that the linguistic phenomena that were dealt with in discourse representation theory can also be treated in such a way that the need to postulate an essential intermediate level of representation does not arise. Methodologically and philosophically, this is of importance, since postulating a representational level means to assume a language of thought as an intermediary between language and interpretation. It leads to a mentalistic theory of meaning, inheriting all the philosophical problems that come with such a view. All other things being equal, a theory that allows one to remain neutral on this issue is preferred.

Concerning interpretation, we concentrated on discourse representation theory. The interpretation procedure in file change semantics is different, and it is not so clear that the critique dynamic semantics puts forward against discourse representation theory applies in precisely the same way to file change semantics.

Dynamic Predicate Logic

The typical type of phenomena that discourse representation theory and file change semantics are designed to deal with are exemplified in the following two examples:

(3) A man is walking in the park. He whistles.

(4) Every farmer who owns a donkey beats it.

In standard predicate logic such (sequences of) sentences are a problem. Appropriate translations are as follows:

(5) $\exists x(\text{man}(x) \wedge \text{walk}(x) \wedge \text{whistle}(x))$

(6) $\forall x \forall y ((\text{farmer}(x) \wedge \text{donkey}(y) \wedge \text{own}(x,y)) \rightarrow \text{beat}(x,y))$

The problem with (5) as a translation of (3) is that the translation of the second sentence in (3) has to be brought under the scope of the existential quantifier in the translation of the indefinite in the first sentence. The problem with (6) as a translation of (4) is that the indefinite, which occurs in (4) inside the relative clause in the subject, turns up in (6) as a universal quantifier that scopes over the implication as a whole. Both facts are problematic from a compositional point of view: the logical formulae are composed at odds with the composition of the sentences. From a compositional point of view, we prefer the following formulae as translations:

(7) $\exists x(\text{man}(x) \wedge \text{walk}(x)) \wedge \text{whistle}(x)$

(8) $\forall x((\text{farmer}(x) \wedge \exists y(\text{donkey}(y) \wedge \text{own}(x,y))) \rightarrow \text{beat}(x,y))$

But, under the standard interpretation of predicate logic, these formulae do not express what (3) and (4) express, because the last occurrence of the variable x in (7) and the last occurrence of y in (8) are free occurrences and are outside the scope of the existential quantifiers.

In a nutshell, what dynamic predicate logic achieves is that the translations in (7) and (8) are appropriate translations of (3) and (4), and, in fact, are logically equivalent with (5) and (6), respectively. It succeeds in this by giving a different, dynamic interpretation to the logical constants of the language of predicate logic. The basic feature of the dynamic existential quantifier is that it can bind variables outside its syntactic scope. This is done by interpreting formulae as transition relations between assignments (of values to variables) much in the same way that programs can be viewed as transition relations between machine states (as seen above). That two assignments a and b are related means that when a is an input assignment, b is a possible output assignment. So formulae are interpreted as such input–output relations. Conjunction is interpreted as the composition of the transition relations of the left and the right conjunct. For example, the output of interpreting ‘ $\exists x(\text{man}(x) \wedge \text{walk}(x))$ ’ will consist of assignments that assign an object to x which is both a man and is walking. In interpreting (7) as a whole, these assignments are passed on as input to ‘whistle(x)’ and will remain as output for the whole sequence if the value assigned to x is also an object that whistles.

For (8) the story is slightly more complicated. Possible outputs for ‘ $(\text{farmer}(x) \wedge \exists y(\text{donkey}(y) \wedge \text{own}(x,y)))$ ’ are assignments that assign a particular farmer to x and donkey to y so that that farmer owns y . The effect of processing the implication ‘ $(\text{farmer}(x) \wedge \exists y(\text{donkey}(y) \wedge \text{own}(x,y))) \rightarrow \text{beat}(x,y)$ ’

is that it is checked to see whether every output of the antecedent still has an output after it has served as input for the consequent. In other words, it is checked whether the farmer in question beats all the donkeys that he owns. So, in effect, an existential quantifier inside the antecedent of a conditional amounts to universal quantification over the implication as a whole. Finally, the contribution of the universal quantification over farmers performs the check we just described for every farmer.

The empirical results that dynamic predicate logic obtains for these sentences are precisely the same as those of discourse representation theory and file change semantics, but the tools being used are much more orthodox. Dynamic predicate logic uses the familiar language of predicate logic, and the only difference in the interpretation of the language compared with the standard interpretation is that assignments of values to variables – which are the result of existential quantification – are remembered beyond the syntactic scope of such quantifiers.

Of course, even small changes can have rather big consequences. The logical properties of the system of dynamic predicate logic differ quite radically from those of standard predicate logic.

Update Semantics

Whereas the dynamic semantics of programs and predicate logic were originally formulated in terms of transition relations between states or assignments, update semantics gives a more simple and intuitive way of viewing the dynamics of interpretation. Statements are interpreted in terms of update functions on information states (or contexts, as they are sometimes called). Schematically, the interpretation of a sentence ϕ in an information state s , written as $s[\phi]$, results in a new state t , which now incorporates the information provided by ϕ .

In the simplest case, information states are modeled as sets of possible worlds (as they are used in modal logic). Since our information about the world is usually partial, an information state leaves several possibilities for the way the world could be. If a world w is an element of a state s , this means that w is a way that the actual world could be, according to the information embodied by s . An update $s[\phi]$ will in general lead to a state t such that $t \subseteq s$. Adding information eliminates possibilities. Growth of information makes the information state shrink.

Truth and falsity are not central notions in update semantics. Sentences are not statically evaluated with respect to the world but are interpreted in terms of their effects on information states. Two special cases of such effects are $s[\phi] = \emptyset$ (the empty set), and $s[\phi] = s$.

The former means that updating s with ϕ leads to the *absurd state*, a state in which there are no possibilities left. This typically happens if ϕ is *inconsistent with* the information embodied in s . When $s[\phi] = s$, this means that the update of s with ϕ has no effect. The sentence ϕ provides no new information relative to s . In such cases we say that s *supports* or *accepts* ϕ .

Now, clearly, update semantics gives us an alternative format to spell out the interpretation of a language, as compared to the standard truth conditional approach, but what are the advantages of this alternative view? One way to motivate update semantics is that there are types of sentences that do not obviously have truth conditional content, but that have meanings that can be described in terms of their effects on information states. Perhaps not the best, but certainly the simplest case to illustrate this with, is provided by epistemic modalities such as ‘might.’ Consider the following example:

- (9) It might be raining outside It isn’t raining outside.

The dots indicate that between the utterance of the two sentences some time passes during which, say, the speaker walks to the window to look outside. The point about the example is that this is a consistent, or coherent, piece of discourse. But at the same time, the following is not:

- (10) It isn’t raining outside It might be raining outside.

This would be hard to explain if both sentences were analyzed in terms of truth conditions (for example, using standard modal logic for the analysis of the modality). Since they are composed of the same two sentences, how could the truth conditions of both sequences differ? From an informational dynamic semantic perspective, it is quite clear what makes the difference. Updating the first sentence of (10) leads to an information state in which there are no worlds left where it is raining at this moment. Such an information state would be inconsistent with the second sentence in (10). (The counterfactual ‘It might have been raining’ is all right, of course.) If things are presented in the opposite order, as in (9), we do not meet this problem. As long as our information state leaves open the possibility that it is raining outside, we can happily accept the first sentence in (9). And neither do we need to have a problem in accepting next the information that it isn’t actually raining.

That order matters is a distinctive feature of update semantics, and of dynamic semantics and dynamic logic in general. Also, in the case of anaphoric relations, order is obviously important. The use of an anaphoric expression, such as a pronoun or

anaphoric definite description, is only felicitous in case the preceding discourse has provided a suitable discourse referent to link it to.

Presuppositions

Dynamic semantics is not only suited to give an account of how the information or the context is changed – by eliminating possibilities and adding discourse referents – but also to formulate the conditions that the current information state or context should meet for a sentence to be acceptable at that point in the discourse. Updates in update semantics are typically partial in that they are only defined in states that meet certain requirements. If a sentence has certain presuppositions, it is required that these are already supported or accepted in the current state, and hence do not provide novel information.

Among the different dynamic frameworks, file change semantics most explicitly takes both anaphoric relations and presuppositions into account. Definites, in particular anaphoric definites, are associated with the property of *familiarity*. In terms of the file card metaphor, a definite requires the presence of a card that already carries the information presented in its descriptive content. In contrast, indefinites carry a *novelty* constraint, and should add a new file card to the stock.

The notion of presupposition has a long and complicated history in logical semantics. Without claiming that all puzzles have already been solved, it seems fair to say that the shift from truth conditions to information change and context change potentials has made a substantial contribution to the study of this phenomenon on the border of semantics and pragmatics.

Further Reading

A much more extensive introduction and overview of dynamic semantics and dynamic logic is Muskens, Van Benthem and Visser (1997). Chierchia (1995) provides an introduction in dynamic semantics with emphasis on linguistic motivation. Groenendijk and Stokhof (2000) gives an informal introduction of dynamic semantics, illustrating it with several different kinds of discourse phenomena.

Discourse representation theory was first presented in Kamp (1981). For an extensive overview, see Van Eijck and Kamp (1997); for a full textbook, see Kamp and Reyle (1993). The original sources for file change semantics are Heim (1983, 1989). An important source of inspiration, for dynamic semantics in general, and for Heim in particular, is Stalnaker (1974, 1979).

Dynamic predicate logic was first presented in Groenendijk and Stokhof (1991). A more detailed study of the dynamics of existential quantification can be found in Dekker (1993). A merge of dynamic predicate logic with Montague grammar is given in Groenendijk and Stokhof (1999). A similar merge with discourse representation theory is proposed in Muskens (1995).

The original source for update semantics is Veltman (1996). In Groenendijk, Stokhof and Veltman (1996), the combination of dynamic predicate logic and update semantics is discussed. An extensive overview of the study of presuppositions in dynamic semantics is given in Beaver (1997).

E-Language versus I-Language

E-Language/I-Language Distinction

The purpose of this article is to clarify the various dimensions of Noam Chomsky's distinction between I- and E-language, with an aim to seeing what is fundamental to that distinction and to discussing some considerations that suggest one or the other conception of language to be correct. The main conclusions are that an E-language conception can and should absorb many of the insights of the I-language conception and that, so enriched, a genuine E-language conception can function foundationally in a theoretical understanding of language.

Some Preliminary Characterizations

Noam Chomsky (1986) introduces the distinction between I-language and E-language with subsequent writings revisiting and clarifying the distinction (e.g., in the papers collected together in Chomsky, 2000). The distinction concerns the metaphysical status of language, of what language is. I-language is internalized, individualistic, idiolectal, and intensional (Chomsky, 2000: 70–73). Each of these features will be discussed in turn, followed by a discussion of the contrasting features of E-language.

Linguistics is to be “conceived of as the study of I-language” and so “becomes part of psychology, ultimately biology” (Chomsky, 1986: 27). To say that a speaker knows a language is to say “the speaker knows an I-language as characterized by the linguist’s grammar” (1986: 27; 40). I-language should be distinguished from Universal Grammar, which we might think of, roughly, as the innately given framework of any human language (*see Innate Knowledge*); I-language is not this initial state of the language faculty but rather “the system of knowledge attained” (1986: 26) at a state of linguistic maturation. I-language is not determined by how speakers use the language, although language use is evidentially relevant for determining the properties of the initial

state and of I-language (cf. George, 1989: note 20). Chomsky also rejects the idea that the language that one speaks is determined by one’s ability with the language (Chomsky, 1980: 51ff.; 1986: 9–21; 2000: 50–52). Rather the language a person speaks is determined by the person’s psychology, in particular by the I-language that is the object of the person’s knowledge. I-language is internalized in being a psychological property of speakers.

I-language is idiolectal in character. The identity conditions for I-languages make no mention of a shared socio-historical object, like English or French, of which speakers have only a partial knowledge. Chomsky (e.g., Chomsky, 2000: 72–73) also rejected Putnam’s (1975) and Burge’s (1979, 1982) antiindividualist ideas that meaning is partially determined by the social and physical environment (*see Externalism about Content*). More will be said about the issue of individualism and antiindividualism below.

Finally, I-language is intensional in the sense that the identity conditions of languages are determined by strong rather than weak equivalence of the grammars that generate them (Chomsky, 2000: 26). Roughly, grammars are weakly equivalent when they generate the same class of expressions as well formed; they are strongly equivalent when they generate the same class in the same way.

I-language is to be contrasted with E-language, which is external, sociolectal, antiindividualist, and extensional. It is external in that the object of E-language study is “a collection of actions, or utterances, or linguistic forms (words, sentences) paired with meanings, or as a system of linguistic forms or events,” perhaps determined by convention (Chomsky, 1986: 19) (*see Conventions in Language*). It is sociolectal in making the primary object of study a social rather than individual-focused object. It is anti-individualist in that it takes the social environment and the physical environment to be relevant to the determination of meaning. And it is extensional in construing languages as identical if the grammar pairs the same sentences with the same meanings, no matter how those sentences or meanings are generated (Quine, 1970).

Getting at What's Fundamental

In order to get at what is fundamental to the distinction between I- and E-language, this article will consider how much of the I-language perspective E-language theorists can accept without compromising their view. As it turns out, the E-language position can accommodate quite a lot. It is noteworthy that the E-language positions described here are either already prominent in the literature or involve natural extensions of the E-language outlook.

Consider first the intensionality of grammar. It is surely part of Chomsky's interest in advocating I-language to rid the study of language of the vestiges of behaviorism; but it is not clear that a quasi-behaviorist conception of language, in which semantic competence consists in dispositions to use sentences under certain conditions, cannot accommodate the intensionality of I-language. Behavioral patterns of semantic acquisition and decay can favor one grammar over some weakly equivalent alternative. If dispositions to use sentences are gained or lost in chunks, that can count in favor of grammars that construe those chunks as wholes grammatically structured in one way rather than another (cf. Evans, 1981 and Davies, 1981b). The same E-language conception shows that the idiolectal aspect of I-language can also be accommodated. The only relevant behavioral dispositions may be that of the individual at a given time. So, a grammar with one structure rather than some other structure weakly equivalent to it can be determined as the grammar of a person at a time. If this is correct, then the intensionality and idiolectal character of language are consistent even with a quasi-behaviorist conception of language and are thus consistent with the overall E-language perspective.

What makes the quasibehaviorist view illegitimate from the I-language perspective? Here other features of I-language are relevant, in particular, the requirement that I-language be internalized. Suppose that the internalization requirement is construed in such a way that in contrast with the quasibehavioral view, that it demands a genuine mentalism; the quasibehavioral conception of I-language is rejected because it fails to be genuinely psychologically realistic. But, again, it seems as though the E-language conception can accommodate I-language requirements. For example, in Lewis's account (1975), language is convention based, and the existence of convention is a psychological matter. Very roughly, in Lewis's account conventions are intentionally propagated regularities among the speech, beliefs, and intentions of speakers and hearers. The point is not the details but rather the fact that conventions are defined partly in terms of the psychological states of individuals. If convention-based conceptions of language are E-language conceptions,

then E-language conceptions of language can accommodate the internalization requirement of I-language when that requirement is interpreted as a requirement to construe language psychologically.

But perhaps there is a stronger way to interpret the internalization requirement. The internalization requirement does not ask merely that language be psychological; it asks that language have a special cognitive home – that language be the object of a special, modularized, faculty of knowledge, the 'language faculty,' that is deployed in speakers' epistemic accomplishments of acquiring the capacity with language and with producing, and perceiving meaning. Language is what is mentally represented in our faculty of linguistic knowledge.

Two aspects of the language faculty should be distinguished. First, the states of the language faculty are tacit and thus differ substantially from ordinary cognitive and conative states such as belief and desire (see **Tacit Knowledge**). Convention-based views of language can accommodate this and perhaps should insist on it. There is at least some *prima facie* case for considering the complicated intentions involved in convention as of a psychologically different kind from the usual, garden-variety intention. Second, and more relevant here, the linguistic faculty is to be a faculty of knowledge of language and thus is a cognitive state directed toward the linguistic facts. Convention-based accounts of language deploy psychological states in the account of convention and may even deploy tacit states, but they do not deploy cognitive states that represent the linguistic facts. That is what the linguistic faculty does. So, the idea is, convention-based accounts of language cannot be I-language accounts because they reject the cognitivism fundamental to the internalization requirement of I-language.

So far we have seen that the intensional and idiolectal, requirements of I-language can be accommodated by E-language conceptions, as can the psychological and tacit aspects of the internalization requirement. But convention-based versions of E-language cannot accommodate the cognitivist aspect of internalization. Can any E-language conception? Again, the answer seems to be affirmative. Indeed, once we move to understanding the internalization requirement as a cognitivist requirement, the E-language conceptions seem to be in its element. States of the language faculty represent the linguistic – the phonological, syntactic, and semantic – facts. Plausibly these facts, like other facts, are facts independent of the thinker. So there seems to be some clear sense in which there is something external about language.

All of this appears to be correct, and it clarifies the issues further. But it doesn't adjudicate the issue between E- and I-language. It fails to do so because

the issue between I- and E-language concerns, not whether the language or the grammatical facts are represented by the language faculty, but rather why some language, rather than some other, is represented by the speaker. The central issue is about the metasemantics of the representations of the language faculty. So even if the facts are external, in the sense that any cognitivism demands, it might well be the case that a speaker stands in a particular representational relation to a language because of facts that are internal to the speaker. The actual language relation may be internally determined.

Individualism and Antiindividualism

This brings us to the final requirement of the I-language conception: that language is not only internalized, but internalist, or individualist, in character. Here we arrive at issues that are fundamental to the debate between I- and E-language. The I-language claim is that language is individualist in the sense that the facts that determine one's language supervene on internal bodily states; the metasemantics of the representation of language is individualist.

According to this kind of individualism, the role of representational content in the states of the language faculty is not questioned; however, it is demanded that the account of why the cognitive states of the language faculty represent what they do appeal only to internal facts. Facts about the language are not identified with facts in the head (for discussion see Rey, 2003a, 2003b) but rather are supervenient upon such facts. However, when this individualist view is applied to semantics, it seems to have the consequence that semantics cannot be referential or truth conditional (*see Truth Conditional Semantics and Meaning*). Representing the referential or truth conditional properties of expressions seems to require standing in some relation to external items of reference, where, in many cases, the external items are external items in the environment. But these relations to external items are not acceptable from an individualist point of view. So it seems that if individualism about semantic cognition is correct, theories of reference and truth can form no part of the content of semantic cognition.

One suggestion for a nontruth-conditional semantics, offered by Ray Jackendoff (1983, 1986), construes the central semantic notion not as truth but as truth-in-a-mental-projection, which is not a replacement for truth but a property that is contrasted with it. In this view, everyday speakers see, speak, and think only of a mentally projected world. This suggestion forces us to deny the instances of the platitudinous T-schema that Tarski (1944) used as a criterion of adequacy for a definition of truth:

(T) *s* is true-in-L iff *p*

where '*s*' is to be replaced by a structural description of a sentence of some language *L*, and '*p*' is to be replaced by the very same sentence (type) in use, or a translation of that sentence. The schema is platitudinous insofar as its use as an adequacy condition is an expression of the platitudinous idea that a sentence is true if and only if things are as use of the sentence says they are. This idea constitutes our fundamental grip on the concept of truth, and it links the concept of truth to the concept of what a sentence says or means (cf. Rattan, 2004) (*see Truth: Theories of in Philosophy*). But in Jackendoff's view, a use of a sentence specifies only a truth-in-a-mental-projection condition, a notion that Jackendoff explicitly contrasts with truth. The view avoids truth conditionalism about meaning, but at too high a cost.

A better suggestion is offered in Pietroski (2003). Pietroski does not deny that language use connects up ultimately with truth (this is its difference from Jackendoff's view). But Pietroski exploits the ambiguity of '*says*' in the platitude about truth to suggest that the platitude is a pragmatic, rather than a semantic, platitude. Indeed, a sentence is true iff things are as a use of the sentence says they are, but in this view, words don't say things, speakers do. Speakers exploit nontruth-conditional properties of expressions to say things, with certain communicative intentions, in certain contexts, that have truth conditions. And, consistently with individualism, the nontruth-conditional properties of expressions are determined by facts inside the head. I-language, including its semantics, is an elaborated, internally determined syntax.

Semantic Intuitions in Linguistics and General Epistemology

This view may ultimately be the most compelling. However, there are grounds for reservation. These grounds center on the role of intuitions in semantics and epistemology (*see Epistemology and Language*).

Intuitions have long been thought to play a fundamental role as data in linguistic theory. These intuitions concern matters of syntax (intuitive judgments of grammaticality or acceptability) and semantics (intuitive judgments of truth conditions). But once the link to truth conditions is broken, the connection between our intuitive judgments about what seems to be a fundamental dimension of what expressions mean – their truth conditions – and semantic theory becomes much more tenuous and theory-involving. Now it may well be that the connection is tenuous and theory-involving, but it would be a mistake to think that this gap simply parallels matters in syntax. In the case of syntax, judgments of grammaticality are overturned based on considerations that have to do with psychological contingencies; for example,

with parsing strategies ('garden-path' sentences) and interactions between memory and syntactic complexity (repeated center-embedding). But if semantics is not truth conditional, then intuitive judgments of truth conditions fail to engage the domain of semantics at all. The failure is not determined by psychological contingencies but rather is preordained by the framework of linguistic theorizing.

Semantic intuitions have another, related role to play in thought. One dimension of Quine's attack (1951) on the analytic/synthetic distinction is on the idea that there is a class of propositions whose truth is grounded in meaning, rather than, as with other true propositions, in worldly fact. Semantic intuitions must then play a dual role in telling us (indirectly) about the language, insofar as the intuitions derive from semantic competence, and also about the world, in being about the world. The second aspect of this dual role can be seen, for example, in the role that semantic intuitions play in correcting lexical explications (Burge, 1986). Considered explications of the meanings of lexical items might determine characteristics that are neither necessary nor sufficient for falling in the extension of, say, *chair*. One traditional, Platonic use of semantic intuitions deploys them to correct mistaken characterizations through the application of lexical items to examples. This deployment is epistemically valuable even when epistemically excessive features often associated with intuitions, like indefeasibility, are stripped away. The general role of semantic intuitions in correcting and being corrected makes sense only against the backdrop of a truth conditional conception of meaning – when there is something that the semantic intuitions intuit or fail to intuit. The epistemic role of semantic intuitions is another casualty of construing semantics in a nontruth-conditional manner.

Empiricism

J Prinz, University of North Carolina, Chapel Hill, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

The term ‘empiricism’ refers to a group of related philosophical doctrines, which place special emphasis on perception or experience. On one traditional formulation, empiricists hold that there is nothing in the intellect that is not first in the senses. This idea has roots in the texts of Aristotle and other ancient philosophers, but it was most influentially developed and defended by the British empiricists of the 17th and 18th centuries (see Locke, 1690; Hume, 1739). Empiricism took on new forms in the twentieth century. The history of Western philosophy can be usefully viewed as an extended debate between empiricists and rationalists.

Species of Empiricism

Empiricists say that experience is primary. But primary in what sense? There are several possible answers: primary as a source of knowledge; primary in the makeup of mental concepts; and primary in linguistic meaning. Each of these answers corresponds to a distinct species of empiricism. This article explains all three in turn.

In epistemology, empiricism is the doctrine that knowledge is based on experience (or ‘*a posteriori*’). Some epistemological empiricists claim that all knowledge is based on experience, some claim that most knowledge is, and some merely insist that the paradigm cases of knowledge are based on experience.

Historically, epistemological empiricism was contrasted with epistemological rationalism: the view that knowledge derives from intuition or pure reason. Rationalists claim that knowledge can be derived prior to experience (or ‘*a priori*’), and, to make good on this claim, they typically assume that we have an extensive stock of innate ideas. In ancient Greek philosophy, Aristotle and Plato inaugurated the debate between epistemological empiricists and rationalisms. Aristotle emphasized the role of observation in learning, whereas Plato emphasized innate knowledge that is acquired prior to birth and either triggered by experience (in the way that a memory might be triggered by seeing a related cue) or else revealed through philosophical reflection. In modern British philosophy, epistemological empiricism was resuscitated by Francis Bacon. Scientific method, he argued, depends on testing hypotheses against experience. Some empiricists have been willing to grant that certain domains are known *a priori*. John Locke

holds this view of ethics and mathematics. Other empiricists have been more thoroughgoing. Moral sense theorists, such as Francis Hutcheson, postulate a special faculty that uses the passions – a kind of sense – to detect ethical truths. Empiricists about mathematics claim that we obtain mathematic knowledge by observation. It has been claimed that we can observe basic truths of geometry, arithmetic, and even set theory.

Epistemological empiricists typically endorse both a causal thesis and a normative thesis. According to the causal thesis, knowledge is causally obtained through experience. For example, Hume says that we obtain knowledge by association: We associate ideas of things that are experienced in spatial or temporal proximity. Associationism exerted an influence on behaviorism and connectionism. Behaviorists say we obtain knowledge by conditioning, which occurs when a stimulus or emitted behavior is accompanied by a behavioral reinforcer. Connectionists believe that knowledge acquisition involves the modulation of weighted connections between layered populations of neurons.

The normative thesis endorsed by epistemological empiricists says that experience is the primary source of epistemic justification. This thesis has often taken the form of epistemic foundationalism: the idea that knowledge must always be justified with reference to things that can be known directly. According to some foundationalists, the only things that we know directly are sense data: perceptual experiences given to us when our sense organs are stimulated (Ayer, 1936). Knowledge that goes beyond direct experience must be based on sense data. For example, Bertrand Russell (1912) argued that we obtain knowledge of the external world by inductive inference: We postulate a mind independent reality because it offers the best explanation of the fact that sense data seem to be outside our control. We might experience the shape of a cat, and then turn away, only to find that the shape remains when we return our gaze to the original position. The best explanation of this is that there is a cat in that location and it exists even when we are not viewing it. Some empiricists, who grant that all knowledge must be sense-based, find this argument unpersuasive; they are driven to skepticism about the external world or to the view that the external world is nothing but a collection of ideas (a view known as idealism or phenomenalism).

Epistemological empiricists need not be foundationalists. W. V. O. Quine (1951) claimed that theories must be confirmed against experience in entirety, rather than confirming a privileged class of

observational judgments and deriving the rest from those. Quine's alternative to foundationalism is called confirmation holism. On this approach, a judgment gains its epistemic warrant from experience along with its coherence with all the other judgments that have been supported by experience and pragmatic rules guiding theory revision. William James and John Dewey also defended versions of epistemological empiricism without foundationalism.

Epistemological empiricism can be distinguished from concept empiricism, the view that all of our concepts (or 'ideas') are derived from percepts (or 'impressions'). Ideas are encoded in the representational formats that are used by the senses. Aristotle said there is no idea without an image. John Locke and David Hume argued that ideas are abstracted or copied from impressions. This doctrine has had a recent revival in cognitive science (see Barsalou, 1999; Prinz, 2002). In addition to our external senses, concept empiricists admit that we can form ideas on the basis of 'reflection,' or inner experiences, such as the passions and sentiments. For example, Hume tried to explicate the concept of moral goodness by appeal to the sentiment of approbation.

Concept empiricists typically reject the rationalists' contention that many ideas are innate. Instead, ideas derive from 'impressions' (the mental states caused in our senses when we perceive the world). According to Locke, some ideas are simply stored copies of impressions, some are combinations of impressions, and some are derived from impressions through abstraction: a process (or set of processes) by which we extract general ideas from experiences of particulars.

In addition to epistemological and concept empiricism, there is an empiricist doctrine relating to meaning. Semantic empiricists contend that the meaning of every linguistic expression must be specifiable using expressions that ultimately get their meaning from experience. One version of this view is the principle of verifiability, which was defended by the logical positivists in the beginning of the twentieth century. According to this principle, a sentence is meaningful only if it can be confirmed or falsified by experience. All meaningful sentences use expressions that refer to things that can be directly observed (observation terms) or things that can be inferred from observable things (theoretical terms).

They allowed one kind of exception, however. The positivists drew a distinction between sentences that can be confirmed by experience (synthetic truths) and sentences that are true in virtue of the meanings of their terms (analytic truths). The sentence 'all mothers are female' is analytic, because 'mother' means female parent. The sentence 'Madonna is a mother' is synthetic. Analytic truths are, in a sense,

knowable *a priori*, but they need not violate the spirit of epistemological empiricism. Analytic truths are based on relations between words that are stipulated by the authors of a language. To accept *a priori* knowledge of such truths is not a concession to the rationalists' claim that we have *a priori* access to substantive truths about the world. Nevertheless some epistemological empiricists reject analytic truths. Quine famously argued that no truth is immune from empirical refutation. New discoveries or events can lead us to revise apparent tautologies. If cross-dressing men began to adopt children and conform to prototypical maternal roles, then we might begin to refer to them as 'mothers.' Thus, 'all mothers are female' would be refuted.

These forms of empiricism often have been defended as a package, but they are independent. For example, an epistemological empiricist might reject concept empiricism and instead adopt the view that concepts are couched in a nonsensory language of thought. A concept empiricist might reject epistemological empiricism and argue for a coherentist theory of justification instead of foundationalism. Concept empiricists and epistemological empiricists might replace semantic empiricism with a causal theory of meaning, which would allow reference to unobservable entities.

Empiricism and Language

Each empiricist doctrine has implications for the study of language. This is most obvious in the case of semantic empiricism, which is a thesis about linguistic meaning. The link between epistemological empiricism and language is most remote, because theories of justification are usually held to be independent of theories of meaning. For verificationists, however, these two dimensions collapse, because meanings are equated with conditions for obtaining knowledge. Some verificationists were led by epistemological considerations (the impossibility of confirming entities hidden from view) to their thesis about meaning.

The connection between concept empiricism and language depends on the relationship between concepts and meanings. Some authors believe that concepts are private mental representations and that meanings are either mind-independent properties and propositions or public rules of linguistic behavior. Other authors believe that meanings are at least partially constituted by the concepts in our heads. Those in this latter camp would claim that an empiricist theory of concepts entails a form of empiricism about semantics. Concept empiricism would entail that meanings are at least partially constituted by perceptually derived mental representations.

Some cognitive scientists try to bridge concept empiricism and semantic empiricism by collecting evidence that people spontaneously use perceptual representations when understanding words and phrases (see, e.g., Barsalou, 1999). A related synthesis can be found in the work of some cognitive grammarians. They argue that some meanings are based on conceptual knowledge and that some concepts are partially constituted by image schemas. Image schemas are schematic (i.e., nonmetric) representations of spatial relations that are used in perceiving the world. George Lakoff (1987) has argued that highly abstract concepts, which are believed to pose a challenge for empiricists, are understood by means of metaphorical extension from perceivable spatial relations. The concept of ownership, for example, is understood with reference to the relation of spatial containment.

Some concept empiricists explain our mastery of abstract concepts in a different way. They argue that public language can be used as vehicles of thought. Sentences are observable. If concepts are stored records of experiences, they can be stored records of experiences with public linguistic items. To understand an abstract concept, on this approach, is to master a set of verbal entailments. Benjamin Whorf and Edward Sapir may have been led to their hypothesis of linguistic relativity in virtue of accepting a picture like this.

Another topic of concern to empiricists is language acquisition. Because empiricists traditionally reject innate ideas, some have argued that language can be acquired using general-purpose perceptual learning rules (such as pattern recognition, association, and conditioning). This view is highly controversial.

Noam Chomsky and his followers have developed powerful arguments for the conclusion that language acquisition requires innate learning mechanisms that are specifically designed for language. Chomsky is a self-proclaimed rationalist, and some empiricists hope to prove that his arguments are mistaken.

In sum, empiricism is a family of doctrines united by the central role they afford to experience. These doctrines often have been defended by the same authors, but they are actually independent. Each has several forms, each faces different challenges, and each has implications for the nature of language.

Empty Names

B Caplan, University of Manitoba, Winnipeg, Canada

© 2006 Elsevier Ltd. All rights reserved.

Most names refer. For example, the name 'Uma Thurman' refers to Uma Thurman. But some names don't refer. For example, suppose that Keanu Reeves introduces the name 'Sparkie' to refer to the lighter in his pocket, if there is one, and to nothing otherwise. If it turns out that Keanu's pockets are empty, then 'Sparkie' doesn't refer. In that case, 'Sparkie' is an *empty name*. Usually, an empty name is empty because there is no object for it to refer to. This is

the case with 'Sparkie': 'Sparkie' is empty because Keanu's pockets are empty. But sometimes an empty name is empty not because there is no object for it to refer to but rather because of something else: the speaker's intentions, say. For example, some philosophers think that although fictional characters exist, names from fiction are empty when they are used with the intention of telling a story. On this view, there is a fictional character that *we* can use the name 'Sherlock Holmes' to refer to when we intend to talk about Sir Arthur Conan Doyle's work, but when *Conan Doyle* uses that name to tell a story, it's empty.

The term 'empty name' goes back at least to the German mathematician and philosopher Gottlob Frege (1848–1925), who called expressions that don't refer 'empty' (or, in German, *leer*). The problems that empty names pose go back much further, at least to the Greek philosopher Parmenides (5th century B.C.E.), who argued that you cannot say of what does not exist that it does not exist. Empty names have been giving philosophers headaches ever since.

The Problem of Negative Existentials

Consider a subject-predicate sentence of the form $[\alpha \varphi]$, where α is the subject and φ is the predicate. $[\alpha \varphi]$ says, of the object that α refers to, that it has the property that φ refers to. And $[\alpha \varphi]$ is true if and only if what it says is the case: that is, if and only if that object has that property. For example, (1) says, of the object (or, in this case, person) that 'Uma' refers to, that it has the property that 'is a movie star' refers to.

(1) Uma is a movie star.

'Uma' refers to Uma, and 'is a movie star' refers to the property *being a movie star*. So (1) says, of Uma, that she has the property *being a movie star*. Since Uma has that property, (1) is true. Now consider (2), which says, of the object that 'Sparkie' refers to, that it has the property that 'doesn't exist' refers to.

(2) Sparkie doesn't exist.

The predicate 'doesn't exist' refers to the property *not existing* (or *being nonexistent*). (2) is a *negative existential*, since it appears to say of some object that it doesn't exist. The trouble with negative existentials is that some of them seem true; but it's hard to see how any of them could be. For example, (2) seems true. But since 'Sparkie' is empty, there is no object that it refers to; so there is no object for (2) to say, of it, that it has the property *not existing*. As a result, it is hard to see what, if anything, (2) says. And if (2) doesn't say anything, then it is hard to see how it could be true.

More generally, negative existentials are a problem for anyone who thinks that (a) the truth value of a sentence is determined, compositionally, on the basis of some semantic feature or features of its parts, and (b) the relevant semantic feature of a name is its referent. (And many philosophers share these assumptions: for example, Fregeans, Millians, and Davidsonians all can accept [a] and [b].) Since an empty name has no referent, it seems to follow that negative existentials that contain empty names have no truth value. This is a problem, because such negative existentials seem true.

Millianism

Empty names pose a number of problems in particular for Millianism. According to Millianism, sentences express *propositions*. These are abstract objects that are the primary bearers of truth values. They are also the objects of attitudes, such as believing and asserting. According to Millianism, propositions are *structured*. This means that the proposition expressed by (1), for example, can be represented as the ordered pair $\langle U, \text{being a movie star} \rangle$, where U is something that corresponds to 'Uma.' (In what follows, complications about what goes in the non-U slot are glossed over; it is assumed that what goes in that slot is a property.) And, according to Millianism, sentences that contain names express *singular* propositions if they express any propositions at all. This means that, in the proposition expressed by (1), U is Uma herself. The proposition expressed by (1) can then be represented as $\langle \text{Uma}, \text{being a movie star} \rangle$.

The source of the problems that empty names pose for Millianism is that it seems that Millianism entails that a sentence that contains an empty name doesn't express any proposition at all. According to Millianism, propositions are structured; so, if (2) expresses a proposition, then that proposition can be represented as $\langle S, \text{not existing} \rangle$, where S is something that corresponds to 'Sparkie.' And, according to Millianism, sentences that contain names express singular propositions, if they express any propositions at all; so, if (2) expresses a proposition that can be represented as $\langle S, \text{not existing} \rangle$, then S is the object that 'Sparkie' refers to. But, since 'Sparkie' is empty, there is no object that it refers to. So there is no object in the S slot in $\langle S, \text{not existing} \rangle$. As a result, it seems that there is no singular proposition for (2) to express and hence that, according to Millianism, (2) doesn't express any proposition at all. The view that sentences that contain empty names don't express any proposition at all is called the *No Proposition View*.

The No Proposition View apparently has a number of consequences that are apparently counterintuitive. For example, you might think that a sentence is meaningful only if it expresses a proposition. If that's right, then the No Proposition View entails that (2), for example, is meaningless. But (2) doesn't seem meaningless. This problem is called the *Problem of Meaningfulness*. Or you might think that a sentence inherits its truth value from the proposition it expresses. If that's right, then the No Proposition View entails that, for example, (2) and (3) have no truth value.

(3) Keanu believes that Sparkie doesn't exist.

But (2) and (3) seem true. This problem is called the *Problem of Truth Value*. Or you might think that a

person can sincerely and assertively utter a sentence only if she believes the proposition that it expresses. If that's right, then the No Proposition View entails that no one can sincerely and assertively utter (2), for example. But it seems that someone could sincerely and assertively utter (2). This problem is called the *Problem of Belief and Sincere Assertive Utterance*. Because of these problems (and others that have to do with the substitution of coreferential names in various linguistic contexts), many philosophers have concluded that Millianism should be rejected in favor of its rival, Fregeanism.

Fregeanism

Fregeanism can solve many of the problems that empty names pose for Millianism. Fregeanism agrees with Millianism that sentences express structured propositions. According to Fregeanism and Millianism alike, the proposition expressed by (1) can be represented as $\langle U, \textit{being a movie star} \rangle$ (again, glossing over what goes in the non-U slot). But Fregeanism denies that sentences that contain names express singular propositions. According to Fregeanism, in the proposition expressed by (1), U is *not* Uma herself. Rather, U is a *mode of presentation* of Uma, MP_{Uma} , something that is a way of thinking about Uma or that captures an agent's perspective on Uma. Perhaps MP_{Uma} is something that picks Uma out by describing her as having certain properties: *being the lead in Kill Bill Vol. 1*, say. Or perhaps MP_{Uma} is some other kind of entity. Where Millians say that the proposition represented as $\langle \textit{Uma}, \textit{being a movie star} \rangle$ is true if and only if Uma has the property *being a movie star*, Fregeans say that the proposition represented as $\langle MP_{\text{Uma}}, \textit{being a movie star} \rangle$ is true if and only if the object that MP_{Uma} presents has the property *being a movie star*. Since MP_{Uma} presents Uma, Fregeans agree with Millians that the proposition that (1) expresses is true if and only if Uma has the property *being a movie star*.

Fregeans can reject the No Proposition View. According to Fregeanism, the proposition expressed by (2) can be represented as $\langle S, \textit{not existing} \rangle$. But, according to Fregeanism, S isn't the object that 'Sparkie' refers to; rather, S is a mode of presentation, MP_{Sparkie} , that corresponds to 'Sparkie.' (If there is such a mode of presentation, then there can be empty modes of presentation: that is, modes of presentation that don't actually present anything. But see **Object-Dependent Thoughts**.) Perhaps MP_{Sparkie} has something to do with the property *being a lighter in Keanu's pocket* and would pick out the unique object that has that property, if there were such an object. Or perhaps MP_{Sparkie} is some other kind of entity.

Fregeans can solve the Problem of Meaningfulness: (2) is meaningful because it expresses the proposition represented as $\langle MP_{\text{Sparkie}}, \textit{not existing} \rangle$. Fregeans can also solve the Problem of Truth Value, at least for belief ascriptions like (3). (3) can be true because Keanu can believe the proposition represented as $\langle MP_{\text{Sparkie}}, \textit{not existing} \rangle$. (How the truth of [3] can be compatible with the assumptions [a] and [b] mentioned earlier is complicated. Perhaps in [3] 'Sparkie' isn't really empty: perhaps in [3] Sparkie refers to MP_{Sparkie} . Or perhaps in [3] 'that' refers to the proposition that [2] expresses.) And Fregeans can solve the Problem of Belief and Sincere Assertive Utterance: speakers can sincerely and assertively utter (2) because they can believe the proposition represented as $\langle MP_{\text{Sparkie}}, \textit{not existing} \rangle$.

But Fregeanism doesn't straightforwardly solve the Problem of Truth Value for sentences like (2). For (2) is true if and only if the proposition that it expresses, the proposition represented as $\langle MP_{\text{Sparkie}}, \textit{not existing} \rangle$, is true; and that proposition is true if and only if the object that MP_{Sparkie} presents has the property *not existing*. But there is no object that MP_{Sparkie} presents, and hence it is not the case that the object that MP_{Sparkie} presents has the property *not existing*. So (2) isn't true. Still, many philosophers think that overall Fregeanism fares better than Millianism in handling the problems that empty names pose.

More Millianism: The Gappy Proposition View

Some Millians reject the No Proposition View in favor of the *Gappy Proposition View*, according to which (2) expresses a *gappy proposition* that can be represented as $\langle _, \textit{not existing} \rangle$. (That proposition is gappy because it is just like a singular proposition except that it contains no object where a singular proposition would.) The Gappy Proposition View can solve the Problem of Meaningfulness: (2) is meaningful because it expresses the gappy proposition represented as $\langle _, \textit{not existing} \rangle$. The Gappy Proposition View can also solve the Problem of Truth Value, at least for belief ascriptions like (3). (3) can be true because Keanu can believe the proposition represented as $\langle _, \textit{not existing} \rangle$. And the Gappy Proposition View can solve the Problem of Belief and Sincere Assertive Utterance: speakers can sincerely and assertively utter (2) because they can believe the proposition represented as $\langle _, \textit{not existing} \rangle$.

But the Gappy Proposition View can't solve the Problem of Truth Value in general. Suppose that Uma introduces 'Markie' to refer to the pen in her pocket, if there is one, and to nothing otherwise. If it

turns out that Uma's pockets are empty, too, then 'Markie' doesn't refer either. On the Gappy Proposition View, (4) and (5) express the same gappy proposition, which is a conditional whose antecedent can be represented as $\langle ___, \text{existing} \rangle$.

- (4) If Sparkie exists, then there is a lighter in Keanu's pocket.
- (5) If Markie exists, then there is a lighter in Keanu's pocket.

But (4) and (5) seems to differ in truth value: (4) seems true, whereas (5) doesn't.

Millians could co-opt some of the resources of Fregeanism and say that agents believe propositions via modes of presentation. (4) and (5) express the same gappy proposition; but there are different modes of presentation associated with (4) and (5). The mode of presentation associated with (4) has something to do with $MP_{\langle \text{Sparkie} \rangle}$, whereas the mode of presentation associated with (5) has something to do with $MP_{\langle \text{Markie} \rangle}$. On this view, (4) seems true, because agents believe, via the mode of presentation associated with (4), the gappy proposition expressed by (4) and (5); but (5) doesn't seem true, because agents don't believe that proposition via the mode of presentation associated with (5). Let's call a Millian view that co-opts Fregean resources in some way *Neo-Millian*.

Still More Millianism: The Communicated Proposition View

Once Millians co-opt Fregean resources and become Neo-Millians, they no longer have to appeal to gappy propositions. Neo-Millians can say that *sentences* that contain empty names don't *express* propositions; but when they use those sentences, *speakers* can *communicate* propositions and in fact speakers can communicate the very propositions that Fregeans say are expressed by the sentences that speakers use. Let's call this view the *Communicated Proposition View*. The Communicated Proposition View can solve the Problem of Meaningfulness: (2) is meaningful because speakers can use it to communicate the proposition represented as $\langle MP_{\langle \text{Sparkie} \rangle}, \text{not existing} \rangle$. The Communicated Proposition View can also solve the Problem of Truth Value: (2) seems true because speakers use it to communicate the proposition represented as $\langle MP_{\langle \text{Sparkie} \rangle}, \text{not existing} \rangle$; and (3) seems true because speakers use it to communicate that Keanu believes that proposition. And the Communicated Proposition View can solve the Problem of Belief and Sincere Assertive Utterance: speakers can sincerely and assertively utter (2)

because they can believe the proposition represented as $\langle MP_{\langle \text{Sparkie} \rangle}, \text{not existing} \rangle$.

The possibility of Neo-Millianism suggests that the debate between Millians (including Neo-Millians) and Fregeans should be understood not as a debate about *whether* there are modes of presentations like $MP_{\langle \text{Sparkie} \rangle}$ but rather as a debate about *where* there are such modes of presentation. Fregeans say that such modes of presentation are constituents of the propositions expressed by sentences that contain names. Millians, by contrast, say that they're not, although they might mediate agents' cognitive relations to propositions (as on the Neo-Millian version of the Gappy Proposition View) or they might be constituents of propositions that speakers communicate (as on the Communicated Proposition View).

Epistemology and Language

H Jackman, York University, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

There has always been a close relation between theories of language, mind, and knowledge, and over the past 80 years, the connection between epistemology and language has typically manifested itself in one of two ways.

First of all, reflection on language has been used to give an account of the meaning of epistemic terms like 'know,' 'rational,' and 'justified,' which have nontrivial, often antiskeptical, consequences. For instance, Strawson (1952) argued that using induction is an essential part of what we *mean* by having 'reasonable' or 'justified' beliefs about the world around us, and so it made no sense to worry about the 'rationality' or 'justification' of induction. More counterintuitively, Malcolm (1952) argued there was a "strong" sense of "know" in which it was impossible for him to doubt that he knew that there was, say, a pen in his hand, since he would have counted *nothing* as evidence against this claim.

This sort of 'ordinary language' approach has generally (and justly) fallen out of favor, as its presuppositions about the meaning of epistemic terms are now viewed as implausible. However, a related strategy that drew from the same Wittgensteinian roots (Wittgenstein, 1969) has emerged in the form of contemporary 'contextualist' epistemologies. These argue that our use of 'know' and related terms is context sensitive in ways that allow the skeptic's claim that we know nothing about, say, the external world *and* our everyday claims to know commonplace facts about the world to *both* be true. It's just that the standards for applying the term 'knowledge' (like those for the application of terms like 'tall') shift from context to context (DeRose, 1995; Williams, 1991).

Such 'therapeutic' approaches do not so much solve traditional skeptical problems as show them to rely upon misunderstandings about how our epistemic terms operate. There is, however, a second way in which philosophical theories of language can be used to respond more 'directly' to traditional epistemological problems.

The second approach focuses not upon the meaning of specific terms, such as 'know,' but rather upon our ability to derive epistemological conclusions from any *general* account of meaning that outlines the limits of our representational capacities. The limits of our representational capacities determine the extent to which certain sorts of skeptical doubts are

legitimate and a general theory of language could thus be used as a weapon against skepticism.

To take an illustrative example, classical verificationism, which understood the meanings of our utterances in terms of the experiences taken to verify them, had clear antiskeptical consequences. If the meaning of a statement like 'there is a pen in front of me' were determined by the experiences standardly used to confirm it, and I could *know* that I'm having such experiences, then I could know that there is a pen in front of me. The verificationist theory of meaning thus blocked skepticism regarding the transition from knowledge of our experience to knowledge of the 'external' world (Ayer, 1936). Of course, it did this at the expense of making problematic our being able to talk or think about anything other than our own experiences.

This general pattern carries over to most other attempts to draw epistemic conclusions from a general theory of linguistic representation. Any substantial account of meaning that treats it as determined by some aspect of our *use* will give a certain amount of epistemic privilege to that meaning-determining aspect, and such privileging may undermine various local or global skeptical worries. However, the antiskeptical advantages that use-based accounts of meaning bring often come at the cost of having to endorse antirealism about facts that we intuitively take to be more 'objective.'

For instance, 'descriptive' theories of meaning took what we meant by (many of) our terms to be determined by (some of) the descriptions we associate with them. 'Pen,' say, gets its meaning by having a description like 'cylindrical handheld artifact used to write with ink' associated with it. However, if such descriptions determined the meaning of the terms involved, then they could be known to be true in virtue of those meanings, and thus a purely 'linguistic' explanation of the possibility of *a priori* knowledge becomes available. We could know *a priori* that all pens are artifacts, because this proposition followed from the meaning of 'pen.' *A priori* truths were so knowable because they were analytic, that is, true in virtue of their meaning (Ayer, 1936).

In addition to the general doubts about analyticity stemming from Quine's work (1951), the description theory suffered from the fact that many of the propositions that it suggested that we knew *a priori* seemed, on reflection, not to be so knowable. There are, as Putnam stressed, things that we *actually* apply the term 'pen' to, and if *they* turned out not to be artifacts (say, they were alien organisms that were born rather than manufactured), then we would conclude that

pens were not artifacts, not that there were no pens (Putnam, 1975). The description theory showed how *a priori* knowledge would be possible, but doubts about such knowledge undermines the descriptive theory itself.

Descriptive theories made the mistake of tying what we mean exclusively to the general characterizations we associate with a term while ignoring what we have actually applied the term to (its 'putative extension'). This would suggest another approach to meaning, one that tied a term's meaning more closely to its putative extension. Such accounts can have antiskeptical consequences as well, but unlike descriptive theories, which seem better suited to underwrite *a priori* knowledge, such accounts underwrite perceptual knowledge.

Tying what a term means to its putative extension (or at least some privileged subset of it) is characteristic of the 'externalist' conceptions of meaning, which replaced the description theories in the 1970s (Kripke, 1972; Putnam, 1975). Such theories were often taken to rule out global skepticism about the external world, since if past usage determined what we meant by a term, then it made no sense to say that we might have always *misapplied* it. If, for instance, we were all brains in vats, and our 'perceptions' had always been determined by a supercomputer we were connected to, then our beliefs and assertions about the 'pens' around us would still be true, since by 'pen' we would mean the *virtual* pens that caused our pen utterances, not the 'real' pens that we hadn't had any contact with (Putnam, 1981). The externalist needn't rule out the kind of scenario that the skeptic traditionally relies on; she just denies that in such a scenario our beliefs would be false.

However, as an antidote to skepticism, such simple versions of externalism face two problems. First of all, even if externalism seems to secure the general veridicality of our beliefs, it does so at the expense of making our knowledge of our own thoughts problematic. After all, if the content of our beliefs is determined by such 'external' factors such as the nature of those items in our environment that we have *actually* applied it to in the past, and we don't have introspective access to such factors, then we may seem to lack introspective access to the content of our own beliefs (McKinsey, 1991; Falvey and Owens, 1994). We may have true beliefs, but our ignorance of their content prevents us from having knowledge. Second, it does seem possible that all of our applications of a term could be misapplications. For instance, there have been many witch sightings throughout history, and since there are no witches, we can assume that all these perceptually based witch beliefs were false. Our general characterization of 'witch' was not

satisfied by any of the people who were called 'witches.' The fact that the meanings of our terms could be affected by these general characterizations makes the transition from externalism to antiskepticism about perceptual judgments problematic. (The same problem emerged with the earlier 'paradigm case' arguments, which also made an attempt to equate a term's meaning with 'uncontroversial' cases of what we actually applied it to.)

The problems with these two sorts of account suggest that one's account of meaning should involve *both* a term's putative extension and the general characterizations associated with it. Something like this combination is found in Davidson's tying meaning to all of the sentences we take to be true, where this class includes both our general beliefs and our dispositions to apply terms to various objects in our actual environment. Davidson insists that on such a holistic account, we must treat a term's meaning as being that which would make *most* of the commitments associated with it true, so his view can still be understood as having antiskeptical consequences (Davidson, 2002). It might be that most of our beliefs about pens were false (because they weren't true of what we actually applied the term to), or it might be that most of the things we called 'pens' weren't pens (because they didn't satisfy most of our central 'pen beliefs'), but it couldn't be the case that *both* sorts of mistakes were the norm.

Still, even if most of our commitments turn out to be true on such an account, there will be no way to tell *a priori* which these will be. The holistic nature of the dynamic between our terms' putative extensions and general characterizations may insure that if our terms pick out anything at all, then the most deeply entrenched elements of our usage will turn out to be correct, but there is no guarantee that any *particular* aspect of a term's putative extension or general characterization will be among the set that ultimately reflects what we mean. Further, the fact that worries about our semantic self-knowledge remain on such an account, and that we can't be sure of the truth of any *particular* belief, suggests again that what the holistic theory gives us is a confidence that most of our beliefs must be true, not knowledge of any particular set of propositions.

It seems, then, that neither analyses of particular epistemic terms such as 'know' nor general semantic theories ruling out widespread misrepresentation can completely put skeptical worries to rest. This may be fortunate, since such strong antiskeptical consequences can be viewed as a sign that a semantic theory treats our representational capacities as *too* constrained and that a more expansive notion of what contributes to meaning is needed (Nagel, 1986).

Essential Indexical

K Romdenh-Romluc, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Indexicals are linguistic expressions such as 'I', 'here', and 'now' whose reference varies depending upon the context in which they are used. Many writers, including Castañeda (1966, 1967, 1968), Perry (1979), and Chisholm (1981), have argued that indexicals are irreducible to other modes of reference, such as names and definite descriptions. 'I' in my statement 'I am hungry,' e.g., cannot be replaced with the co-referring expression 'Komarine' without loss of cognitive impact, since I may believe that Komarine is hungry without realizing that Komarine is me. The same applies to uses of 'here' and 'now.' It is also claimed that the thoughts expressed using indexicals have a privileged role. The central insight is perhaps best appreciated if we consider Perry's claim that indexicals are essential for characterizing beliefs that motivate action (see also Castañeda, 1966, 1967, 1968).

I may see myself in a mirror and notice that the person I see reflected has dirt on her face, but unless I believe that *I* have a dirty face I will not wipe it. I may believe that the meeting starts at noon but will not be moved to act unless I believe that the meeting starts *now*. I may believe that the treasure is buried outside the old church, but I will not start digging unless I believe that the treasure is buried *here*. To act requires me to have beliefs about my surrounding environment and how I am situated with respect to it. Indexical beliefs provide for this because their content is essentially perspectival. It is this egocentric dimension that is lost if the indexical is replaced with a non-indexical term, which is why indexical expressions cannot be reduced to other modes of reference.

Perry (1979) famously argued that indexicals pose a problem for the traditional Fregean account of belief. According to this theory, beliefs are relations between subjects and propositions. The belief report 'Komarine believes that Fido is a dog' states that an individual – Komarine – stands in the relation of believing to the proposition 'Fido is a dog.' The

problem arises because the Fregean view implies (i) propositions are held to be true or false timelessly – not only true or false at a particular time, in a particular place, expressed by a particular person, and (ii) propositions are not individuated only by the ordinary objects that the proposition is about, but also by something like the conceptual components of the proposition that affect its cognitive impact. The propositions ‘Hesperus is Venus’ and ‘Phosphorus is Venus’ are about the same object, the planet Venus, but they are nevertheless different propositions since they are composed of different concepts. It is easy to see why indexicals pose a problem given the need to simultaneously satisfy (i) and (ii). A sentence such as ‘I am hungry’ does not pick out a proposition since its truth-value varies from context to context. To identify the proposition I believe when I utter ‘I am hungry,’ we need to specify some conceptual component associated with the term ‘I.’ To satisfy (i), the specification must yield a proposition that is timelessly true or false; to satisfy (ii), it must preserve the cognitive impact of ‘I am hungry.’ But as we saw above, there is no way of rendering ‘I am hungry’ as a proposition that is timelessly true or false without losing its cognitive impact. Various solutions to the problem have been proposed. Some attempt to refine the traditional account of belief (see, e.g., Evans, 1985), while others reject it in favor of a theory that can deal with the problem (see, e.g., Perry, 1986).

We sometimes attribute a use of an essential indexical to someone else. The usual way to do this is to use an *oratio obliqua* construction. I can, e.g., attribute the thought ‘I am going to be late for work’ to Sue by uttering, ‘Sue thinks that she herself is going to be late for work.’ Similarly, if Richard is in Malaga and thinks ‘It is hot here,’ I can attribute this thought to him by uttering ‘Richard is in Malaga; he says it is hot there.’ If Teresa thinks at 12 o’clock, ‘It is now time to go to the meeting,’ I can attribute this thought to her by uttering, ‘Teresa thought at 12 o’clock that it was then time to go to the meeting.’ (The alternative is to employ an *oratio recta* construction, e.g., ‘Sue thinks: I am going to be late for work.’) Castañeda (1966, 1967, 1968) labels

expressions that attribute a use of an essential indexical to someone else in *oratio obliqua* constructions ‘quasi-indicators.’ Like essential indexicals, quasi-indicators cannot be replaced with co-referring expressions without loss of cognitive impact. ‘Sue thinks that Sue is going to be late for work’ and ‘Sue thinks that she herself is going to be late for work’ attribute different thoughts to Sue, since she may have amnesia and forget that she is called ‘Sue.’ Thus, quasi-indicators raise the same kind of issues as essential indexicals. There are further problems associated with their use. Essential indexicals create difficulties for the traditional Fregean account of belief because the beliefs they express are essentially tied to the perspective of the believer. It is puzzling, therefore, how a listener can grasp the content of another’s indexical utterances, and further, convey that content to someone else. Again, there is disagreement concerning how the content of quasi-indexical attitudes – those expressed using quasi-indicators – should be understood.

Event-Based Semantics

P Lasersohn, University of Illinois at Urbana-Champaign, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

The notion of *events* may be used in semantic theory in a wide variety of ways, but the term *event-based semantics* normally refers to semantic analyses that

incorporate or adapt the proposal of Davidson (1967) that certain predicates take an implicit variable over events as an argument. In Davidson’s original proposal, this event argument is accommodated by analyzing the predicate as having one more argument place than is assumed in more traditional analyses. The event variable is existentially quantified, with the result that Sentence (1)a is assigned a

logical structure like (1)b, rather than the more traditional (1)c:

- (1) a. Jones buttered the toast.
- b. $\exists e$ butter(Jones, the toast, e)
- c. butter(Jones, the toast)

Thus, *butter* is analyzed as expressing a three-place relation between an individual who butters, an object that gets buttered, and a buttering event; and the sentence is analyzed as asserting that such an event exists.

The initial motivation for this proposal is that it provides a way to analyze adjuncts such as locative, temporal, and instrumental adverbial phrases. These are also treated as predicates of events – or more specifically as predicates of the same event as the verb. Each adjunct gives rise to its own clause in logical structure, and these are combined with the clause corresponding to the verb and its arguments by ordinary propositional conjunction. The existential quantifier binding the event variable takes scope over the whole structure, so that Sentence (2)a is assigned a logical structure like (2)b, for example:

- (2) a. Jones buttered the toast with a knife in the bathroom at midnight.
- b. $\exists e$ [butter(Jones, the toast, e) & with(e , a knife) & in(e , the bathroom) & at(e , midnight)]

This approach has an advantage over one in which the adverbials are treated as arguments of the verb, so that *butter* expresses a five-place relation as in (3):

- (3) butter(Jones, the toast, a knife, the bathroom, midnight)

If we adopt a formula like (3), but continue to represent *Jones buttered the toast* as in (1)c, with a two-place relation, we would seem to deny that *butter* expresses the same meaning in both sentences and claim instead that it is ambiguous. Nor is this a simple two-way ambiguity; *butter* will have to express different relations in each of the sentences in (4)

- (4) a. Jones buttered the toast with a knife.
- b. Jones buttered the toast in the bathroom.
- c. Jones buttered the toast at midnight.
- d. Jones buttered the toast with a knife at midnight.
- e. Jones buttered the toast with a knife in the bathroom.
- f. Jones buttered the toast at midnight in the bathroom.

This massive ambiguity is undesirable.

We might try to avoid the ambiguity by claiming that *butter* always expresses a five-place predicate, and that in examples in which fewer than five arguments appear overtly, the missing argument places are filled by implicit existentially bound variables.

However, this strategy ignores the fact that additional adverbials can always be added, with no limit on the number; as long as adverbials are analyzed as arguments, one cannot specify a fixed number of argument places for the verb, even if one allows for implicit arguments.

These problems are avoided completely under Davidson's proposal; *butter* is consistently analyzed as a three-place predicate. An unlimited number of adverbials may be added because these combine with the verb by ordinary conjunction, and not by filling argument places.

A second advantage to this analysis is that it correctly captures the fact that Sentence (2)a entails all the examples in (4) as well as (1)a, that (4)d entails (4)a, (4)c, and (1)a, and so on. Without some extra stipulation, these entailment relations do not fall out of an analysis in which adverbials are arguments to the verb. Extra stipulations are also required to capture these entailment relations in other alternative approaches to the semantics of adverbials, such as an approach in which they are treated as higher-order predicates taking verb intensions as arguments, as in (5):

- (5) [at-midnight(\wedge in-the-bathroom(\wedge with-a-knife(\wedge butter))))](Jones, the toast)

Davidson limited his original proposal to 'action sentences' and was explicit that it should not be applied to sentences such as $2 + 3 = 5$. Nonetheless, it is sometimes assumed that a similar analysis should be extended to some or all stative sentences (see especially Parsons, (1987/1988, 1990). In analyses employing both states and events, the term *eventuality* (introduced by Bach, 1986) is often used for the general category covering both.

The issue of which predicates have a hidden argument place for an eventuality, and which do not, is addressed in a well-known proposal by Kratzer (1995); see also Higginbotham (1983) and Fernald (2000). Kratzer suggests that *individual-level* predicates do not have such an argument place, and that *stage-level* predicates do. This position is supported by the following pattern of acceptability:

- (6) a. When Mary speaks French, she speaks it well.
- b. *When Mary knows French, she knows it well.
- c. When a Moroccan speaks French, she speaks it well.
- d. When a Moroccan knows French, she knows it well.

Assuming that indefinites contribute free variables to semantic representation (as in File Change Semantics or **Discourse Representation Theory**) and that *when*-clauses serve to restrict the domain of an implicit generic quantifier that can bind these variables,

the acceptability of (6)c–d is expected. The unacceptability of (6)b follows from a simple prohibition on vacuous quantification: The *when*-clause contains no free variables for the generic quantifier to bind. Why, then, is (6)a acceptable, as it does not contain any indefinite noun phrases either? Kratzer suggests it is because the stage-level predicate *speak* contributes a free Davidsonian event variable, whereas the individual-level predicate *know* does not.

Another area in which event variables have proven useful is in the semantics of perception reports (Higginbotham, 1983; Vlach, 1983; Parsons, 1990). Sentences like (7)a have been cited in support of thoroughgoing revisions to semantic theory of the kind adopted in **Situation Semantics**; but if we analyze this sentence as meaning that there is an event *e* of Mary's leaving, and an event *e'* of John's seeing *e*, we may assign it the logical structure in (7)b and obtain a reasonable analysis without using resources beyond those of ordinary first-order logic:

- (7) a. John sees Mary leave.
b. $\exists e[\text{leave}(\text{Mary}, e) \ \& \ \exists e' \text{ see}(\text{John}, e, e')]$

Davidson's technique of representing adjunct phrases as expressing separate logical clauses raises the possibility that major arguments of the verb such as the subject, direct object, and so on, might be treated in the same way. Davidson himself rejected this sort of extension, but a variant of it has been very popular in later work. Often termed the *Neo-Davidsonian* approach, this style of analysis treats the verb as a one-place predicate of eventualities; the subject, direct object, and so on do not serve directly as arguments to the verb, but instead stand in thematic relations to an event that fills the verb's sole argument place. A sentence such as (8)a thus receives a logical structure like that in (8)b:

- (8) a. Brutus stabbed Caesar.
b. $\exists e[\text{stab}(e) \ \& \ \text{agent}(e, \text{Brutus}) \ \& \ \text{patient}(e, \text{Caesar})]$

This approach to thematic relations appears first to have been proposed by Parsons (1980, 1985, 1990); see also Carlson (1984) and Krifka (1989, 1992). Note that this style of analysis requires an eventuality argument for all predicates that assign thematic roles, not just action predicates or stage-level predicates – at least on the assumption that thematic roles are represented in a uniform fashion for all predicates that assign them.

One advantage of this approach is that it allows a nice analysis of 'semantically optional' arguments: The direct object of *stab* may be omitted, as in (9)a; to give a logical form, we simply omit the clause for the corresponding thematic relation, as in (9)b:

- (9) a. Brutus stabbed.
b. $\exists e[\text{stab}(e) \ \& \ \text{agent}(e, \text{Brutus})]$

In a more conventional analysis, we might represent this sentence as in (10)a:

- (10) a. $\exists x \text{ stab}(\text{Brutus}, x)$
b. $\text{stab}(\text{Brutus})$

But as Parsons points out, this entails that Brutus stabbed something, whereas (9)a does not: Brutus could have stabbed and missed. If we try to avoid this entailment by representing (9)a as (10)b, we treat *stab* as ambiguous, expressing a different meaning in (9)a than it does in (8)a; but this is avoided in the Neo-Davidsonian analysis.

The idea that verbs are predicates of events has also been exploited in the analysis of certain types of nominalization (Higginbotham, 1985; Parsons, 1990). Combining the Neo-Davidsonian analysis with an assumption that nominals may express the same predicate of events as the verbs they derive from makes it possible to account for the validity of the argument in (11)a in a very straightforward fashion. This argument is represented as in (11)b, which is licensed by standard principles of first-order logic:

- (11) a. In every burning, oxygen is consumed.
Agatha burned the wood.
Therefore, oxygen was consumed.
b. $\forall e[\text{burn}(e) \rightarrow \exists e' [\text{consume}(e') \ \& \ \text{theme}(e', \text{oxygen}) \ \& \ \text{in}(e, e')]]$
 $\exists e[\text{burn}(e) \ \& \ \text{agent}(e, \text{Agatha}) \ \& \ \text{patient}(e, \text{the wood})]$
 $\exists e'[\text{consume}(e') \ \& \ \text{theme}(e', \text{oxygen})]$

Event arguments have also been used extensively in the analysis of Aktionsart. One line of research in this area, exemplified by Pustejovsky (1991, 1995) and Grimshaw (1990), represents events of certain complex types as structurally composed of events of simpler types. For example, an accomplishment predicate such as *build* may be associated with events of the structure illustrated in (12):

Here *e*₁ represents the building process itself, whereas *e*₂ represents the resultant state of something having been built. As a telic predicate, *build* involves reference not just to the building process, but also to its culmination in the transition to a result state, represented by *e*₀.

A rather different approach to the event-theoretic representation of Aktionsart was developed by Krifka

(1989, 1992). Here, a 'sum' operation is assumed on events, so that for any two events e_1, e_2 , a complex event $e_1 \sqcup e_2$ consisting of them is assumed to exist. A part/whole relation is definable in terms of the sum operation: $e_1 \sqsubseteq e_2$ (' e_1 is a part of e_2 ') iff $e_2 = e_1 \sqcup e_2$. Predicates are assumed to denote sets of events, allowing aspectual classes to be defined in terms of closure conditions on these sets. Cumulative predicates are those denoting sets that are closed under the sum operation:

$$(13) \text{ CUM}(P) \leftrightarrow \forall x, y [P(x) \ \& \ P(y)] \rightarrow P(x \sqcup y)]$$

For example, if x is a walking event, and y is a walking event, their combination is also a walking event. In contrast, quantized predicates denote sets from which proper parts of their members are excluded:

$$(14) \text{ QUA}(P) \leftrightarrow \forall x, y [P(x) \ \& \ P(y)] \rightarrow x \not\sqsubseteq y]$$

For example, if x is an event of drinking a glass of wine, and y is also an event of drinking a glass of wine, x cannot be a proper part of y . Cumulative and quantized predicates of events correspond roughly to the familiar categories of atelic and telic predicates, respectively. However, by assuming a sum operation and corresponding part/whole relation on individuals, and not just events, it is possible to apply these concepts to predicates of individuals as well. For example, if x is wine and y is wine, their sum must also be wine, establishing *wine* as a cumulative predicate; if x is a glass of wine and y is a glass of wine, x may not be a proper part of y , establishing *glass of wine* as a quantized predicate. The status of a verb's arguments as cumulative or quantized often affects the aspectual category of the verb phrase or sentence; hence (15)a is cumulative whereas (15)b is quantized:

- (15) a. John drank wine.
b. John drank a glass of wine.

Assuming a Neo-Davidsonian representation of thematic relations, Krifka explored the mathematical properties such relations must have to give this effect.

A related application of part/whole structures for events was developed by Lasnik (1990, 1995) for the semantics of plurality (see also Schein, 1993). Distributive readings of predicates with plural subjects are analyzed as representing events that divide into smaller events corresponding to the individual members of the group denoted by the subject. For example, an event of John and Mary sitting divides into a smaller event of John sitting and one of Mary sitting. Collective readings correspond to events that cannot be divided in this way; an event of John and Mary being a happy couple does not divide into an

event of John being a happy couple and an event of Mary being a happy couple. Representing the collective/distributive distinction in terms of event structure in this way makes possible an extensional analysis of adverbials like *together*, which imposes a collective reading on the predicates it modifies.

Event-based semantics has also been fruitfully applied to a wide variety of other problems, of which space limitations prevent a discussion here: plurality (Lasnik, 1990, 1995; Schein, 1993; Landman, 2000), temporal anaphora and narrative progression (Hinrichs, 1986; Partee, 1984), cognate objects (Mittwoch, 1998), adjectives (Larson, 1998), and many others. There is also a large philosophical literature on events, much of which relates directly to Davidsonian-style event-based semantics; see Davidson (1980), LePore and McLaughlin (1985), Higginbotham *et al.* (2000), and the references cited therein.

Evolution of Semantics

V Evans, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

One of the most important functions of language is to facilitate the 'transmission' of thought from one language user to another. A number of scholars, including Sperber and Wilson (1995), and Tomasello (1999, 2003), have observed that verbal communication requires both a code – which is to say a language-system involving conventional symbols, pairings of form and meaning – and intentional mechanisms such as inference-reading abilities. While both these aspects are essential for verbal communication, communication can, in principle, occur in the absence of a code. Indeed, as we shall see, intentionality and the ability to recognize communicative intentions are likely to have been necessary prerequisites for the evolution of symbolic representation in language.

To function as a means of communication, an important prerequisite of a code, which is to say a language-system, is to be able to encode and externalize humanly-relevant concepts and combinations of concepts. Semantic knowledge, therefore, concerns the range and nature of humanly relevant concepts that can be expressed in language, and the way language serves to combine concepts in order to convey

complex ideas. In this article, we explore (i) possible cognitive preadaptations for the development of semantic knowledge, and (ii) the range and nature of conceptual structure as encoded in language, and suggestions as to the way that this structure may have evolved.

Unlike some other aspects of language, there is scant evidence we can draw on in attempting to reconstruct the evolution of semantic knowledge. After all, we are, in essence, attempting to reconstruct the evolution of human cognition. To do this, we are relying on indirect evidence drawn from primatology and comparative psychology, paleontology, evolutionary anthropology, and evolutionary psychology. Nevertheless, in view of some recent developments in linguistics, both in terms of uncovering and better understanding semantic phenomena, and recent theory-construction, we can now construct some plausible paths of semantic evolution that will at least facilitate further inquiry.

Cognitive Preadaptations for Semantic Knowledge

Language is characterized by being representational or 'symbolic.' That is, a language consists of a structured set of 'symbolic units' consisting of form and

meaning components. While this definition represents the received view for lexical items, a growing body of scholarship argues that grammatical patterns can also be thought of as being inherently symbolic in nature (Langacker, 1987). Symbolic units consist of two further units: a phonological unit and a semantic or conceptual unit. The semantic unit, which is what we are concerned with here, has been variously termed a 'lemma' (Levelt, 1989) or a 'lexical concept' (Evans, 2004). In this section, we approach the evolution of semantic knowledge in a general way by considering the cognitive preadaptations that may have paved the way for the emergence of semantic knowledge.

The Importance of Motor Evolution

Donald (1991, 1999) has argued that there were two essential prerequisites for the evolution of symbolic units. One defining characteristic of language is that it can represent a particular idea or entity in the absence of a concrete cue: the design feature of language known as 'displacement.' For this representation to occur, hominids had to gain conscious access to their own memories (Donald, 1999). A second and crucial preadaptation for the emergence of language was the development of voluntary motor control. That is, hominids must have developed the ability to attend to their own action patterns, and to select, trigger, and 'edit' action pattern sequences. According to Donald, this development gave rise to 'mimesis,' a form of nonlinguistic representation. Mimetic action is representational in that it relies on perceptual resemblance to represent itself. For instance, hominid tool use, which can be traced back 1.5 million years, may have employed mimetic representation not only for showing and learning how to employ a tool, but through 'editing' motor routines through rehearsal, to improve the way in which the tool was used. Forms of representation such as mime, dance, ritual acts, and some kinds of music are also mimetic, serving as a form of communication that is nonlinguistic in nature. According to Donald, mimetic action was the earliest form of communication, upon which the later development of language may have been built.

While voluntary control of the musculature must have been important in the rise of this early and basic form of communication, and presumably also facilitated the later development of phonetic abilities and phonological systems, for Donald, linguistic representation is of a different kind from mimetic representation. While mimetic representation is holistic, a key characteristic of semantic knowledge, as represented by the inventory of lexical concepts available in the languages of the world, is that symbolic units

serve to 'parse' sensory or perceptual experience into component parts, e.g., tree versus rock versus mountain, and even to encode a particular perspective with respect to which a component is viewed. For, instance, 'shore' and 'coast' both encode the same strip of land at the edge of the sea, but do so from different perspectives. Thus, for Donald, the importance of mimetic representation was that it created an appropriate cultural context, what he terms 'mimetic culture,' in which communication took place, and more precise disambiguation could occur with the advent of linguistic representation.

The Importance of Intention-Reading Skills

Another important preadaptation for the development of semantic knowledge is likely to have been the emergence of the ability to read intentions. According to Tomasello (1999), this sort of ability was the crucial preadaptation required for the evolution of symbolic abilities such as language more generally. Research in developmental psychology reveals that during early ontogeny, shortly before a year old, human infants begin to experience themselves as 'intentional agents.' That is, they perceive themselves as beings whose attentional and behavioral strategies are goal-directed. Accordingly, human infants also come to see others with whom they identify, conspecifics, as intentional agents. Crucially, it is shortly after this ontogenetic 'breakthrough' that language begins to emerge (Tomasello, 2003). Later, from around the age of three, human infants begin to develop the notion of themselves and conspecifics as 'mental agents.' This development constitutes the emergence of the 'theory-of-mind,' in which children develop the ability to conceive that others can hold different views from their own.

The importance of viewing oneself and conspecifics as intentional agents is far-reaching. From this view, it follows that others are intentional agents who possess mental states that can be directly influenced and manipulated. For instance, pointing at an object can cause one intentional agent – who recognizes the person doing the pointing as an intentional agent attempting to direct attention – to follow the direction of pointing and thus share a 'joint attentional frame' (Tomasello, 1999, 2003). Thus, from this perspective, the importance of a lexical concept being associated with a particular linguistic form is in the utility of the symbolic unit in affecting the mental state of another in some way, such as by coordinating behavior. In other words, language, and the lexical concepts encoded by language, require intention-reading skills, which derive from the awareness that conspecifics represent intentional agents whose mental states can be influenced and manipulated by language.

A number of scholars view intention-reading abilities as an outcome of earlier evolutionary developments. For instance, Whiten (1999) argued that intention-reading skills constitute the outcome of the emergence of what he termed 'deep social mind.' This result can be characterized by cooperative behaviors including the sharing of food, monogamous reproduction – which has been claimed to be the ancestral pattern for humans – and behavior such as communal hunting. Indeed, Whiten argued that intention-reading abilities would have been essential for coordinating activities such as hunting, success at which requires being able to read the intentions of cohunters, and possibly also the prey.

Intention-reading skills most likely evolved by reading observables, such as direction of gaze, direction of motion, and so on. Thus, intention-reading skills are likely to have emerged from behavior-reading skills. On some accounts, chimpanzees are capable of rudimentary intention-reading abilities. Thus, intention-reading might be more than 6 million years old (Byrne, 1999), the time when hominids and chimpanzees separated.

Some scholars have argued that intention-reading in hominids can be viewed as a consequence of a long chain of evolutionary development. For instance, Savage-Rumbaugh (1994) suggested that bipedalism may have set in chain a series of evolutionary developments that gave rise to the cognitive ability to take the perspective of others (intention-reading). For instance, while chimpanzees and gorillas are distinguished from orangutans by a kind of quadrupedal locomotion termed 'knuckle-walking,' early hominids, the australopithecines, who emerged sometime between 4 and 5 million years ago, were distinguished by bipedalism. According to Savage-Rumbaugh, knuckle-walking and bipedalism were distinct and independent solutions to traversing open terrain and transporting infants. However, a consequence of bipedalism, but not knuckle-walking, is that the parent would have had to pay more attention to the infant, which is carried in the arms. In particular, the parent must remember to pick the child up after it has been put down. This consequence may have led to the later evolution of being able to take the perspective of others.

Similarly, Byrne (1999) argued that there may be more remote evolutionary antecedents for intention-reading abilities. One hypothesis is that our relatively large brachiating ancestors, for whom a fall would have been deadly, may have accomplished arboreal locomotion by advance planning. The mental representation of self as an entity moving through space would have prefigured representational abilities in general, and would have facilitated planning

Table 1 Human intention reading abilities

Human intention reading abilities include . . .

The ability to coordinate or share attention, as when an infant and adult both attend to the same object

The ability to follow attention and gesturing, as when an infant follows an adult's pointing or gaze, in order to attend to an object

The ability to actively direct attention of others, such as drawing attention to a particular object or event, for instance, through pointing

The ability of culturally (imitatively) learning the intentional actions of others, such as imitating verbal cues in order to perform intentional actions such as declarative, interrogative or imperative speech functions

a trajectory of motion. Self-representation, and the ability to consciously plan one's movements are cognitive achievements that imply intentionality, and the later evolution of intention-reading skills. The suite of intention-reading skills evident in modern humans is summarized in Table 1.

The Importance of Personality Types

This issue concerns the idea that the earliest lexical concepts may have related to personality traits (King *et al.*, 1999). Recent research suggests that personality traits are stable across time and between contexts, correlate with verbal and nonverbal behaviors, and can be reliably judged by human observers. Moreover, King *et al.* (1999) argued that such behaviorally-signaled personality traits as reliability, dominance, and trustworthiness are directly relevant to complex social interactions involving competition, cooperation, sharing, sexual selection, and so on. King *et al.* (1999) suggested that it is the context-independent nature of such complex personality traits, and their importance for hominids that suggests such traits may have been encoded as the earliest lexical concepts.

For instance, studies that have sought to teach chimpanzees to manipulate symbolic units have found that for symbol use to succeed, meaning must be de-contextualized. Consider the example of an apple. If a symbol is applied to this referent, it is not clear which properties of the scene the symbolic form relates to. For instance, it could refer to the apple's color, shape, or that it is an item of food. Until the referent has been experienced in a number of contexts, it is not clear which aspect of the referent is being indexed, and thus what the lexical concept is that is being associated with the form. As personality traits are context-independent and readily identifiable by observers, then an early linguistic form that indexed a particular personality trait might have served as an early lexical concept. That is, personality traits achieve the displacement aspect of lexical concepts by virtue of being inherently context-independent.

For this reason, symbolic representation in language may have taken personality traits as the first lexical concepts.

The Nature and Evolution of Semantic Knowledge

In this section, we examine the nature of semantic knowledge in more detail. That is, we examine how humans organize the world and their experience of the world into concepts. We also speculate on possible evolutionary bases of semantic knowledge of this kind and the cognitive mechanisms underlying this knowledge.

Concept Formation

‘Semantic structure’ constitutes the meaning system directly expressed by and encoded in language. In other words, semantic structure is the form that conceptual structure takes for expression in language. Thus, in order to get a sense of the nature of semantic knowledge, for instance, the nature and range of lexical concepts, we must begin by examining the nature of conceptual structure. In this section, then, we consider the basic units of concept structure, ‘concepts.’ We consider the following question: Where do concepts come from?

For psychologists, concepts are the basic units of knowledge and are essential both for ‘categorization’ – the ability to identify individuals, entities, and instances – and ‘conceptualization’ – the ability to construct alternative perspectives (Barsalou, 1992). To illustrate the notion of conceptualization, consider the sentences in (1) and (2). Each provides a different conceptualization of the concept Book:

- (1) That book is heavy.
- (2) That book is boring.

While the example in (1) relates to the book ‘as tome,’ the example in (2) relates to book ‘as text.’

Since the work of the French philosopher René Descartes in the 17th century, who developed the principle of Mind/Body dualism, there has been a common assumption within philosophy and, more recently, the other cognitive sciences, that conceptual structure can be studied without recourse to the body, and hence without recourse to ‘embodiment.’ In modern linguistics, this ‘objectivist approach’ has been most evident in the approach to meaning known as ‘Formal Semantics.’ Proponents of this approach assume that it is possible to study meaning as a formal or computational system without taking into account the nature of human bodies or human experience. This position is problematic from an evolutionary

perspective as it entails that a new discontinuous cognitive adaptation was required for conceptual structure. Conceptual structure, on this account, is assumed to employ what has been termed an ‘amodal’ (nonperceptual) form of representation. Amodal representation is distinct from the ‘modal’ or perceptual forms of representation that presumably had to exist prior to the emergence of conceptual structure, in order to represent ‘percepts’ (Barsalou, 1999).

The last two decades or so have seen a shift from modeling conceptual representation in terms of amodal systems, towards a more perceptual-based or ‘embodied perspective.’ An embodied perspective takes the view that concepts derive from percepts, and thus, conceptual structure is fundamentally perceptual in nature. Within linguistics, this general perspective has been advocated most notably by Lakoff and Johnson (1980, 1999; Lakoff, 1987), and also by Jackendoff (1983, 1992, 2002).

In general terms, the idea is that concepts have an embodied character. This idea constitutes the thesis of embodied cognition (see Ziemke, 2003 for discussion).

The idea that concepts are embodied assumes that we have a species-specific view of the world, due to the nature of our physical bodies.

One obvious way in which our embodiment affects the nature of experience is in the realm of color. While the human visual system has three kinds of photoreceptors or color channels, other organisms often have a different number. For instance, the visual system of squirrels, rabbits, and possibly cats, makes use of two color channels, while other organisms, for instance, goldfish and pigeons, have four color channels (Varela *et al.*, 1991). Having a different range of color channels radically alters how the world of color is perceived. This difference affects our experience of color in terms of the range of colors accessible to us along the color spectrum. Moreover, while some organisms can see in the infrared range, humans are unable to see in this range (Jackendoff, 1992). It’s clear, then, that the nature of our visual apparatus – an aspect of our physical embodiment – determines the nature and range of our visual experience. The position that different organisms have different kinds of experiences due to the nature of their embodiment is known as ‘variable embodiment.’

The position that our experience is embodied – that is, structured in part by the nature of the kinds of bodies/neuro-anatomical structure we have – has consequences for conceptual structure. This corollary follows because the concepts we have access to, and the nature of the ‘reality’ we think and talk about, is a function of our embodiment. In other words, we can only talk about what we can perceive and

think about, and the things that we can perceive and think about derive from embodied experience. Hence, the human mind must bear the imprint of embodied experience.

Some psychologists have made specific proposals as to how embodied experience gives rise to concepts. For instance, the developmental psychologist Jean Mandler (2004) suggested that through a process of ‘perceptual meaning analysis,’ percepts come to be re-coded as concepts. Mandler argued that this process occurs alongside percept formation and begins virtually from birth. However, she viewed percepts and concepts as wholly distinct forms of representation. Another view has been proposed by Barsalou (1999). He argued that a concept is akin to a remembered perceptual state, which he termed a ‘perceptual symbol.’

From an evolutionary perspective, if it is correct that concepts are fundamentally perceptual in nature, then by virtue of early hominids gaining conscious access to the contents of their own memories, little additional complexity in terms of cognitive development is required for a rudimentary conceptual system to have emerged. This corollary follows as concepts, on this account, are something akin to ‘remembered percepts.’

The Nature of Lexical Concepts: The Natural Partitions Hypothesis

Having examined conceptual structure, we now turn to semantic structure.

Linguists have traditionally classified lexical concepts into those that are encoded by ‘open’ versus ‘closed class forms.’ Open class forms include, for English, nouns, verbs and adjectives, while closed class forms include determiners, prepositions, conjunctions, and so on. The basic insight is that it is much harder to add new members to the closed class set than to the open class set. A related insight is that open class forms tend to have much richer denotational meaning, while closed class forms are associated with lexical concepts that have more schematic or relational meaning. That is, they provide connections to other lexical concepts that have a more referential meaning.

However, since at least the early 1980s, the strict separation between closed and open class concepts

has been called into question. This query stems from the observation that the division between open and closed class concepts constitutes more of a continuum rather than a strict bifurcation. For instance, Gentner (1981) pointed out that verbs, which are normally thought of as being open class, are highly relational in nature, a feature associated with closed class elements.

More recently, Gentner and Boroditsky (2001) have elaborated on this view, suggesting that open class lexical concepts exhibit ‘cognitive dominance.’ This contrasts with closed class concepts that exhibit ‘linguistic dominance.’ These notions relate to the similar idea expressed by Langacker (1987), who used the terms ‘conceptually autonomous’ versus ‘conceptually dependent.’ The basic idea is that lexical concepts associated with prototypical open class (autonomous) forms obtain their reference independently of language, which is to say from the world, while prototypical lexical concepts associated with closed class or relational forms obtain their reference from language. Moreover, whether a form is cognitively dominant (or autonomous) or linguistically dominant (or dependent) is a matter of degree. A proposed continuum is given in Figure 1.

In order to account for the cognitive dominance of prototypical open class lexical concepts (i.e., nouns), Gentner (1981) proposed the Natural Partitions Hypothesis. This idea holds that concepts that are encoded as prototypical open class elements such as individuals and objects are ‘individuated.’ That is, entities of this kind constitute densely bundled collections of percepts. Thus, an entity such as a rock or a tree ‘stands out.’ In Gestalt Psychology terms, a rock constitutes the figure in the figure-ground organization of a given scene. The Natural Partitions Hypothesis states that certain aspects of the world are given by the world. These entities are typically encoded crosslinguistically by nouns, and are acquired first by children. On this account then, bundles of percepts are ‘given’ by the world, and are simply labeled by language.

The Natural Partitions Hypothesis offers an intriguing insight into a possible order of evolution among lexical concepts – which is to say concepts encoded by language. That is, we might speculate, based on this, that the very first lexical concepts were those for

Figure 1 Division of dominance among form classes of lexical concepts. (Adapted from Gentner and Boroditsky, 2001: 216.)

individuals, including animals (and possibly classes of animals) and objects. Concepts of this kind have the most cognitive dominance. That is, they have highest conceptual autonomy. Other lexical concepts may have evolved later.

Further, there is a correlation between the position of a lexical concept on the continuum of dominance (see Figure 1) and the form class associated with the lexical concept. Although this correlation is not exact, for instance, ‘destruction’ and ‘destroy’ encode a similar concept employing different lexical classes (noun versus verb), it is plausible that the evolution of lexical classes (or ‘parts of speech’) emerged due to distinctions in the relative dominance or autonomy being further, later, encoded by morphosyntactic properties of language.

Lexical Concepts and Concept-Combination

From an evolutionary perspective, being able to form concepts and express them via language, while a remarkable achievement, doesn’t begin to approach the range and complexity of the semantic structure available to modern Homo Sapiens. Lexical concepts are only a subset of our semantic knowledge. Another important aspect of semantic knowledge concerns our ability to combine lexical concepts in order to give rise to new and different kinds of conceptual structure. Moreover, it is a striking fact that concept combination produces complex concepts that are not simply the sum of the individual parts that comprise the derived concept. For instance, the complex concept *Petfish* is not simply the intersection of the concepts *Pet* and *Fish*. Rather, the concept *Petfish* has its own concept-internal structure, known as ‘category structure.’

For instance, while most people would rank mackerel, which is silver in color, as a good example of the *Fish* category, a cat or a dog would be rated as a good example of the *Pet* category. Yet, a good example of a *Petfish* is a goldfish. Not only is a goldfish not silver, it is not soft and cuddly either. An important task in developing an evolutionary perspective on semantic knowledge is to account not only for the way in which lexical concepts are formed, but also for the mechanisms responsible for concept combination.

A recent approach to concept combination of this kind argued that complex concepts result from a process of ‘conceptual integration’ (Fauconnier and Turner, 2002; Turner and Fauconnier, 1995). This process involves what is termed ‘selective projection’ of content from each of the concepts that give rise to the complex concept, as well as additional material derived from background knowledge, such as knowledge that the kinds of fish we keep in fishbowls are typically goldfish. This process is termed ‘completion.’ Thus, the complex concept, known as a ‘conceptual blend,’ has structure associated with it that is found in neither of the ‘input’ concepts that give rise to it. This structure is diagrammed in Figure 2.

Clearly, some form of conceptual integration allows humans to combine and manipulate concepts in order to produce more complex ideas. Fauconnier and Turner argued that the emergence of cognitively modern human beings, during the upper paleolithic era, somewhere in the region of 50 000 years ago, points to the development of a new cognitive ability: our ability to perform conceptual integration. While anatomically modern humans appear to have existed from at least 100 000 years ago, the upper paleolithic stands out. This period witnessed the emergence of

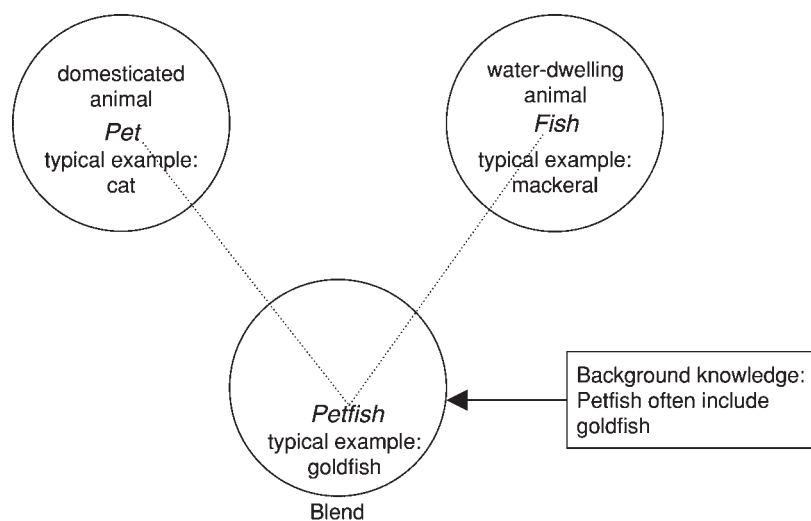

Figure 2 Conceptual integration for the composite concept *goldfish*.

new social and technological breakthroughs, including the development of projectile points made from bony material for use in hunting, the manufacture of personal adornments, the development of sophisticated art, evidence of belief systems such as religion and magic, plus manmade shelters were built for the first time, sewn clothing was worn, and sculptures were produced. Fauconnier and Turner argued that what made advances such as these possible, was that humans had evolved the ability to perform complex conceptual integrations. This process, then, may have facilitated composing and elaborating concepts to produce new and more elaborate conceptual structures.

Polysemy

Another striking aspect of semantic knowledge is the phenomenon of ‘polysemy.’ This aspect constitutes the way in which a range of related lexical concepts can be expressed using a single form. For instance, the English preposition ‘over’ has a number of distinct but related lexical concepts associated with it. Consider some of the distinct lexical concepts proposed by Tyler and Evans (2003):

- (3a) The picture is over the sofa [‘above’]
- (3b) The picture is over the hole [‘covering’]
- (3c) The ball is over the wall [‘on-the-other-side-of’]
- (3d) She has a strange power over him [‘control’]
- (3e) The government handed over power [‘transfer’]
- (3f) She prefers wine over beer [‘preference’]
- (3g) The relationship is over [‘completion’]
- (3h) The relationship evolved over the years [‘temporal’]
- (3i) The fence fell over [‘reflexive’]
- (3j) They started the race over [‘repetition’]

Recent research has argued that polysemy, far from being merely a ‘surface’ phenomenon, is in fact conceptually real. That is, polysemy patterns reflect distinct lexical concepts, stored as different senses in the mental lexicon (Evans, 2004; Lakoff, 1987; Tyler and Evans, 2003). Accordingly, from an evolutionary perspective, the challenge is to explain how the proliferation of lexical concepts, i.e., polysemy, arises.

A recent perspective is that polysemy emerges from the interaction between language use and contexts of use, due to the conventionalization of situated (or invited) inferences (Traugott and Dasher, 2002; Tyler and Evans, 2003; Evans, 2004). For instance, the ‘covering’ meaning associated with ‘over’ may have derived from contexts of use in which, in a given spatial scene, an element placed above another entity thereby covered it. Through a process of decontextualization, the ‘covering’ meaning was reanalyzed as

being a distinct meaning component. Once this reanalysis occurred, it could be used in novel ways unsupported by the original spatial scene that gave rise to the inference in the first place (Tyler and Evans, 2003).

From an evolutionary perspective, the importance of polysemy and meaning-extension is that it illustrates how language, in conjunction with human experience, can give rise to new lexical concepts. Moreover, this particular phenomenon of meaning-extension illustrates how language can flexibly increase its repertoire of lexical concepts without increasing the number of linguistic forms.

Abstract Concepts

Another important aspect of semantic structure relates to so-called abstract concepts. These include lexical concepts such as Truth, Justice, or Theory. Concepts of these kinds are abstract in the sense that they cannot be straightforwardly accounted for in terms of perceptual recording, precisely because it’s not clear what their perceptual basis is, and even whether they have one. Indeed, abstract concepts provide a significant challenge if we are to attempt to provide an evolutionary account maintaining the thesis of embodied cognition.

An influential framework that provides an account that is based in perceptual or embodied experience is the ‘conceptual metaphor theory’ of Lakoff and Johnson (1980, 1999). Lakoff and Johnson argued that abstract concepts are grounded in embodied experience, and thus our perception of the world, even if the grounding is not direct. This grounding is achieved by virtue of ‘conceptual metaphors,’ which are long-term conceptual mappings that serve to project structure from a ‘source concept,’ which relates to perceptual experience onto the abstract concept, the ‘target concept.’ For instance, we commonly understand the abstract concept of Quantity in terms of the more perceptually concrete concept of Verticality, as evidenced by examples such as the following:

- (4a) The price of stocks has **gone up**.
- (4b) Her score is **higher** than mine.

In both these examples, an abstract notion of Quantity is understood in terms of physical position or motion on the vertical axis. This understanding is licensed by the conceptual metaphor Quantity Is Vertical Elevation.

The most recent version of conceptual metaphor theory recognizes two distinct kinds of conceptual metaphors: ‘primary metaphors,’ which are directly grounded in experience and constitute ‘primitive’ conceptual mappings, and more complex ‘compound metaphors,’ which are constructed out of the more

experientially basic primary metaphors (Grady, 1997; Lakoff and Johnson, 1999).

For instance, when we understand Theories in terms of Physical Structures, as evidenced by the following examples:

(5a) Is that the **foundation** for your theory?

(5b) The argument is **shaky**.

Grady argues that the motivation for linguistic examples such as these is in fact two primary metaphors, Persisting Is Remaining Erect and Organization Is Physical Structure. These unify to give the compound metaphor An Abstract Organized Entity [such as a theory] Is An Erect Physical Object (Grady, 1997).

Thus, it is only primary metaphors that are grounded in perceptual experience. The motivation for the conceptual associations captured by primary metaphors is due to a tight and ubiquitous correlation in experience. For instance, there is a tight and recurring correlation in experience between quantity and height. When we fill a glass with water, an increase in quantity correlates with an increase in height. Thus, primary metaphors are motivated by 'experiential correlation.'

From an evolutionary perspective, the phenomenon of 'metaphoric' mappings holding between concepts from different parts of 'conceptual space,' known as 'domains,' allows us to account for how perceptual information can be recruited in order to construct more abstract concepts, such as Quantity and Theories. This phenomenon suggests that, in addition to being able to recode percepts as concepts and combine concepts, the conceptual system must have additionally developed a mechanism for projecting structure from one conceptual domain to another in order to create more abstract concepts.

Cultural Evolution

The final issue we examine is that of cultural evolution. Lexical concepts are culturally embedded, and thus, we must briefly look at the role of cultural evolution in providing the conceptual backdrop for the emergence of semantic knowledge.

Consider the evolution of the concept of Money. This concept is one that has been evolving for over 3000 years. Weatherford (1998) identified a number of key mutations in the development of how we conceptualize Money. The first was the invention of coins in Anatolia over 3000 years ago. This development gave rise to the monetary economies that underpinned the classical Greek and Roman civilizations. The second was the development of family-owned credit banks in Renaissance Italy. This development gave rise to capitalist market economies that replaced earlier feudal societies throughout Europe, and

the period in which European countries expanded to become global economic powers. The process whereby cultural artifacts or cultural practice undergoes cumulative evolution, resulting in modification or improvement has been dubbed the 'ratchet effect' (Tomasello, 1999). Thus, an important aspect of the evolution of semantic knowledge involves the development and evolution of cultural knowledge.

Evolution of Syntax

B Clark, Middlesex University, London, UK

R Jackendoff, Brandeis University, Waltham, MA, USA

After more than a century of more or less avoiding the subject, linguists have become much more interested in questions about evolution in recent years. Arguably, this interest was kick-started by an important paper by Steven Pinker and Paul Bloom (Pinker and Bloom, 1990). The number of articles in this encyclopedia that are concerned with matters of evolution can be seen as evidence of this increased interest (see cross-references below). Jackendoff (2002: 231–232) suggests two reasons for the increased interest. One is that we now understand much more about evolutionary principles in general and about human origins in particular than we did a century ago. The other is that increased interest in evolution in general inevitably leads to increased interest in the evolution of language in particular and, as Bickerton suggests (Calvin and Bickerton, 2000), it is important for linguists to be involved in this discussion. At the same time, there is some ambivalence about this topic. Linguists are wary of debates on topics where the data is so limited and the discussion therefore has to be quite speculative. Despite this, there have been a number of interesting discussions in recent years and significant progress has been made in this area. There has also been a significant increase in work that considers how syntax in particular might have evolved. This essay begins by considering some general questions about the nature and evolution of language before considering questions about the evolution of syntax, and some of the answers that have been proposed. The two sets

of questions are closely linked in ways that echo the connections between studies of language in general and studies of syntax in general.

Language

Before working out how a particular trait evolved, we first need to know what that trait is. There has been considerable disagreement about what 'language' is in the past and there are currently several different views (see the articles in this encyclopedia on **Linguistics: Approaches**). Language can be viewed as a social or a cultural phenomenon as well as a psychological one. But any social or cultural phenomenon must be represented mentally, and psychological systems and processes must be involved at some stage in the spread of any phenomenon through a culture.

Even when seen as a psychological phenomenon, there is disagreement about what kind of thing language is, and different assumptions about this will have implications for theories of language evolution. To take one example, Hauser *et al.* (2002) claim that recursion is the one key feature of language seen as a mental faculty, while Pinker and Jackendoff (2005) see recursion as just one of several important properties of language. At a more general level, there is the question of how components of the language system such as phonology (the system of sounds), syntax (structure), and semantics (representations of meaning) are related. Could phonology exist independently of syntax? Could syntax exist independently of phonology? Could the use of symbols exist without the existence of structural representations? Even more generally, there is the question of how language relates to other parts of the mind. Fodor's 'language

of thought' hypothesis (Fodor, 1975) suggests that our system of mental representations is both representational (has a kind of semantics) and computational (has a kind of syntax). If this is so, then we need to explore how the language of thought relates to our knowledge of natural languages, including the relationship between the syntax of the language of thought (which most theorists would assume to be universal) and the syntax of particular languages.

Evolution of Language

One of the most frequently discussed questions about the evolution of language concerns the speed at which it occurred. Was it a slow, incremental process where each stage developed independently after the previous one? Or did language emerge suddenly as something dramatically different from what had gone before? Another question concerns the nature of the evolutionary process. Pinker and Bloom (1990) suggest that language is a complex biological adaptation that evolved by natural selection, while other researchers have considered evolution as a cultural phenomenon rather than a biological one. Pinker and Bloom's work is partly motivated as a response to Chomsky's (1975) skepticism about an evolutionary account of language based on natural selection. While many researchers agree that a number of preadaptations made the development of language possible, there is disagreement on whether language emerged as an adaptation (so that language is now being used for the purpose for which it evolved) or, following Gould's (1991) terminology, an exaptation (where a trait that evolved for one purpose is then co-opted for another purpose). An exaptation can be either an adaptation that has been co-opted for a purpose different from that for which it originally evolved (such as feathers, which originally evolved because they helped keep birds warm but later turned out to be useful for flight) or side effects of adaptations, which then turn out to be useful in a different way. The latter are referred to as 'spandrels,' a term taken from architecture where it describes the spaces created as a side effect of putting two arches next to each other. Gould suggests that language could be a spandrel in the sense that it is a by-product of increased brain size that was beneficial for independent reasons. This view seems to be supported by Chomsky in one of his most well-known comments on evolution:

We know very little about what happens when 10^{10} neurons are crammed into something the size of a basketball, with further conditions imposed by the specific manner in which this system developed over time. It would be a serious error to suppose that all properties, or the interesting properties of the structures that

evolved, can be 'explained' in terms of natural selection. (Chomsky, 1975: 59)

Another general question concerns the relationship between the different features that together constitute human language. One important problem in developing an account of the evolution of language has to do with the perceived complexity of language and the large number of separate phenomena that together are involved in linguistic behavior: at least phonology, syntax, and semantics for the system itself, and at least intentionality and metarepresentational ability for the ability to communicate with it. While it is easy to see that full human language is likely to deliver an evolutionary advantage and so be favored by natural selection when it happens to emerge, it is not so obvious that any of these phenomena alone would deliver an evolutionary advantage. So it seems unlikely that a situation could arise where what we know as language could emerge and then be selected. This may be one reason for Chomsky's reluctance to entertain the possibility of an account of language evolution based on natural selection.

Partly despite and partly in response to this problem, discussion has focused on particular components of language and there has been ongoing discussion of the likelihood of various orders of emergence. Lieberman (1984, 1991, 1998), for example, has suggested that the ability to speak preceded the development of full language. He suggests that we first evolved all of the physiological resources to make speech possible and that this then made possible the development of full language. Corballis (2002), in contrast, suggests that fully syntactic messages were conveyed by hand gestures along the lines of modern signed languages long before speech developed. Bickerton (2003) rejects Corballis's view, following Burling (2000) and Sperber and Origgi (2000) in assuming that prehumans had to be attempting some form of intention-recognition before any of the components of language could exist. While he suggests that symbolism might have preceded structure by "as much as two million years" (Bickerton, 2003: 81), he also suggests that syntax is central to language and that this was the crucial development which made language possible. Okanoya (2002) suggests that syntax might have developed before words so that semantic relationships emerged after syntactic structure. This is based on evidence from the study of finch song, where it seems that a rudimentary syntax evolved independently of meaning. Okanoya further suggests that there are links between syntactic abilities and sexual selection.

An account of the evolution of syntax will be located within this debate and will have to address the

question of how syntax and its evolution relate to other components of language and their evolution.

One major issue for all work on evolution is the nature of the evidence. In work on the evolution of language, there is a wide range of approaches from a wide range of disciplines using a wide range of evidence types. Areas that provide, or could conceivably provide, evidence include animal communication, anthropology, archeology, artificial intelligence, cognitive neuroscience, comparative neuroanatomy, computer modeling, ethology, formal language theory, language acquisition, language disorders, mathematics and mathematical modeling, philosophy, psychological experiments, as well as more familiar linguistic and conceptual evidence. But of course since language itself leaves no fossils, all evidence is indirect.

Syntax

As suggested above, we cannot but assume that syntax is part of language seen as a psychological phenomenon (even if syntax-like combinatorial structure is also involved in thought and other aspects of the mind). So an account of the evolution of syntax must be part of an account of the evolution of language seen as a psychological phenomenon. As well as answering questions about the relationship between syntax and other components of language, any account of how syntax evolved will need to make assumptions about the nature of syntax itself and how it is related to other parts of the mind. Different answers to these questions lead to quite different accounts of the evolution of syntax. At one extreme, we might suggest that syntactic structure (in the sense of NPs and VPs) is necessary for combinatorial thought, and therefore that syntax is a necessary precursor to the development of full human language. At another extreme, we might suggest that syntactic structure emerges after the development of other phenomena such as the ability to speak and the ability to understand noises or gestures as representing particular meanings. To some extent, this is a question of the development and status of combinatoriality. Combinatoriality is a property of phonological and semantic knowledge, as well as of syntax. This raises the question of whether it arose in one of these areas first before developing in the other areas.

Chomsky has suggested that the properties of phonological structure and of semantic representations each depend on properties of syntax but not *vice versa*. In his view, syntax is fundamental to our linguistic knowledge. Jackendoff (2002) terms this 'syntactocentrism' and argues that it should be rejected.

He proposes that language can be understood in terms of a 'parallel architecture' where phonology, syntax, and semantics are separate, equally generative, components that communicate with each other through 'interface' components. This question concerns us here because of the implications for an account of the evolution of syntax. Can we treat the evolution of syntax as separate from the evolution of phonology and semantics or do they depend on each other, mutually or in an ordered way (where the evolution of one preceded the evolution of the other)?

Recursion is a fundamental property of syntax, and an important part of an evolutionary account will concern how knowledge of recursive structures such as (1) evolved:

- (1) Keith said that Billy thought that this was the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

What makes this recursive is the fact that it contains constituents that dominate other instances of the same syntactic category (for example, the sentence beginning *Keith said that...* dominates the sentence beginning *Billy thought that...*)

It is not only linguistic expressions that demonstrate recursion. Our thoughts too are recursive, in that we can embed thoughts within other thoughts, entertaining propositions such as that expressed by (2):

- (2) Tom thinks that Mary said that Dan was wondering whether Frieda knew about the party.

It seems that we are the only creatures who have this ability to such an extent. Other primates can entertain thoughts about thoughts but only to a limited extent (see Tomasello and Hare, 2003), e.g., a chimp might be able to think that if he defends an empty container, another creature will think it is full; or recursive thoughts might be involved in a chimp working out a plan of action. This is, though, about as complex as such thoughts can get for chimps. Humans can entertain recursive thoughts quite easily and can also produce and understand linguistic expressions that are complicated in the same way. This leads to speculation that the evolution of syntax may have made possible both metarepresentation and also human language.

Evolution of Syntax

There has been a considerable amount of significant work on the evolution of syntax in recent years

(a large amount of this work can be found in the collections edited by Christiansen and Kirby, 2003; Hurford *et al.*, 1998; Knight *et al.*, 2000; Wray, 2002). While no general consensus or dominant approach has yet emerged, we can identify a number of questions and themes that researchers have addressed. As mentioned above, many of these concerns overlap or mirror questions about the evolution of language as a whole. It is not possible here to do justice to the range of positions and themes that have been explored so far, but we run through a number to give a flavor of the kinds of issues currently being explored. At the end of this section, we give a more detailed sketch of Jackendoff's (2002) sketch of a possible series of stages in the evolution of (syntax and) language.

Is Syntax Adaptive?

As with other components of language, there are different views about whether syntax is adaptive or not, and therefore whether it can be explained in terms of natural selection or not. Pinker (2003; Pinker and Bloom, 1990) and Bickerton (1981, 1990, 1998, 2002, 2003), among others, suggest that language and syntax are adaptive and so amenable to an account in terms of natural selection. Lightfoot (1991, 2000), in contrast, suggests that some properties of syntax are not adaptive and so they have evolved despite being dysfunctional. Part of the evidence is that individuals violate some of the constraints imposed by the syntactic system. Lightfoot argues that certain conditions are “dysfunctional, blocking expressions which are needed” (Lightfoot, 2000: 244). This means that they are spandrels and so could not have been selected for. He concludes that this is true of at least some syntactic conditions but does not rule out the possibility that the whole language system is a spandrel. Overall, a number of distinct positions have been taken with regard to the question of whether syntax, or language, is adaptive. The notion that syntax is adaptive is often linked to the observation that combinatoriality is a property not only of syntax but also of semantics, phonology, and thought.

Exaptation

Assuming a biological approach, one suggestion that has a significant number of supporters is that syntax is an exaptation from nonsyntactic structure. One possible line on this is that the mental representations involved in thought developed combinatorial structure and this was then taken over by the linguistic system. Alternatively, combinatoriality might have

originated in phonology or in speech (Carstairs-McCarthy, 1999).

Biological or Nonbiological Evolution

Related to this is the question of whether explanations are proposed in terms of biology, of culture, or as developments within the language system itself. As we have seen, Bickerton and Pinker propose a biological account. Tomasello (2003) shares one part of Bickerton's view, namely that it is the separate evolution of symbols and grammar that distinguishes human communication from that of other primates. But he rejects Pinker's and Bickerton's view that it is specifically language that is adaptive. He suggests instead that language emerged as one part of the larger process of the evolution of human culture. In his view, the emergence of a broader kind of social cognition enabled human culture, and human symbolic communication should be seen as a special case of that. Worden (2000) proposes a model with a constant biological endowment which, together with specific learning mechanisms, enables the **cultural** evolution of languages. Hurford (2003) proposes a combination of biological preadaptations and learning-based linguistic adaptations. Jackendoff (2002) leaves open the question of how much is biological and how much cultural.

The ‘Big Picture’ and Details of Syntax

Hurford (2000: 222–224) raises the interesting issue of the relationship between programmatic, ‘big-picture’ statements and “the degree of detailed knowledge that has now been accumulated about the syntax of languages.” He points out, for example, the striking contrast between the simple syntaxes of the emergent languages in computer models and the complexity of real languages, which is familiar to linguists. He suggests that the value of programmatic proposals follows from the fragmented and rapidly changing nature of contemporary syntactic theorizing. The ‘turmoil’ of the field, he suggests, means that syntactic theorizing “needs to start looking beyond its traditional horizons for explanatory principles of kinds that it has not previously considered” (Hurford, 2000: 223).

A related contrast is between programmatic proposals and more specific suggestions. One of the boldest specific suggestions so far has been Newmeyer's (2000) suggestion, based on evidence from typology as well other work on language evolution, that the earliest forms of human language had rigid SOV word order.

Effects of Particular Developments Within Theories of Syntax

It is also interesting to consider how particular developments in syntactic theorizing relate to theories of the evolution of syntax. The Minimalist Program, for example, has been seen by some theorists (e.g., Berwick, 1998) as making evolutionary accounts more plausible, while others, including Chomsky himself (1991a, 1991b) have suggested that language is ‘dysfunctional’ with regard to processing and so makes an evolutionary account less likely. These conclusions rest, of course, on assumptions about how particular syntactic theories interact with other domains, such as theories of processing.

When Did Syntax Emerge?

Many researchers suggest that syntax emerged relatively late (around 40 000–150 000 years ago) and relatively quickly, but Burling (2002) suggests that it may have been a more gradual process starting much earlier. His evidence for this comes from looking at early and late stages of child language acquisition. He suggests that the acquisition of syntax spans a relatively long time in the development of an individual child and that this weakens arguments based on analogy with child language acquisition that the evolutionary development of syntax was abrupt.

How Many Stages?

Related to this is the question of the stages involved in evolution. Bickerton (1990, 1998, 2002, 2003; Calvin and Bickerton, 2000; see also Bickerton’s article in this encyclopedia) has proposed that language evolved in two stages. The second step is the development of language as we know it now. The first step is the development of protolanguage. Protolanguage is a simpler system of communication than full human language where certain actions (sounds or gestures) represent certain meanings but without the full complexity that arises with the development of syntax. So protolanguage can be thought of as ‘modern language without syntax.’

There are two particularly interesting things about this proposal. First, it suggests a way around the logical problem caused by thinking of human language as one entity and so suggests how we can develop an incremental account of language evolution. Protolanguage would bring advantages and therefore ‘be worth selecting for its own sake.’ Second, Bickerton suggests that protolanguage is still present in the human brain and can be seen in a number of situations where language is disrupted or

not developed. Cases of disruption include the development of pidgin languages when distinct language groups are thrown together and need to find a way to communicate without a full shared language (Bickerton, 1981), cases such as that of ‘Genie’ (Curtiss, 1977), where an individual is denied the necessary environmental triggers until it is too late for her to acquire full language, and possibly cases of agrammatic aphasia, language disorders that affect syntactic processing. Cases where language has not developed include early child language and communication systems developed by apes when humans attempt to teach them language (Linden, 1974; Savage-Rumbaugh *et al.*, 1998). The suggestion is that protolanguage emerged, was useful and favored by natural selection and that this made possible the subsequent development of human language with complex syntax.

A Series of Stages

Bickerton (1990) initially saw the development from protolanguage to modern language as one great leap, but has since (Calvin and Bickerton, 2000) developed a more gradualist position. Jackendoff (2002) proposes a much more incremental story. He suggests that it is possible to reconstruct from modern human language a sequence of distinct innovations from primate calls, each of which is an improvement in communicative expressiveness and precision. He suggests, furthermore, not only that the earlier stages are present in the brain but also that their ‘fossils’ are present in the grammar itself, and so are available as evidence. A summary of the steps proposed is shown in **Figure 1**.

Working downward through **Figure 1**, the first step and the two steps on the left of the figure (use of symbols, open class of symbols, phonological combinatorial system) take us beyond primate call systems but do not come close to full modern language. The development of a phonological combinatorial system is an important step here. As the number of symbols becomes larger, it becomes harder to make them all memorable and discriminable. If the symbols were holistic, it would not be possible to keep even a thousand of them distinct in perception and memory. This problem is solved in modern language by building words up combinatorially from a few dozen smaller meaningless speech sounds, the phonemes.

The first step toward modern syntax is to concatenate more than one symbol into a single utterance, with the connection between them determined purely by context. Concatenating more than two symbols multiplies the number of possible meanings, though much depends on exactly which symbols are used.

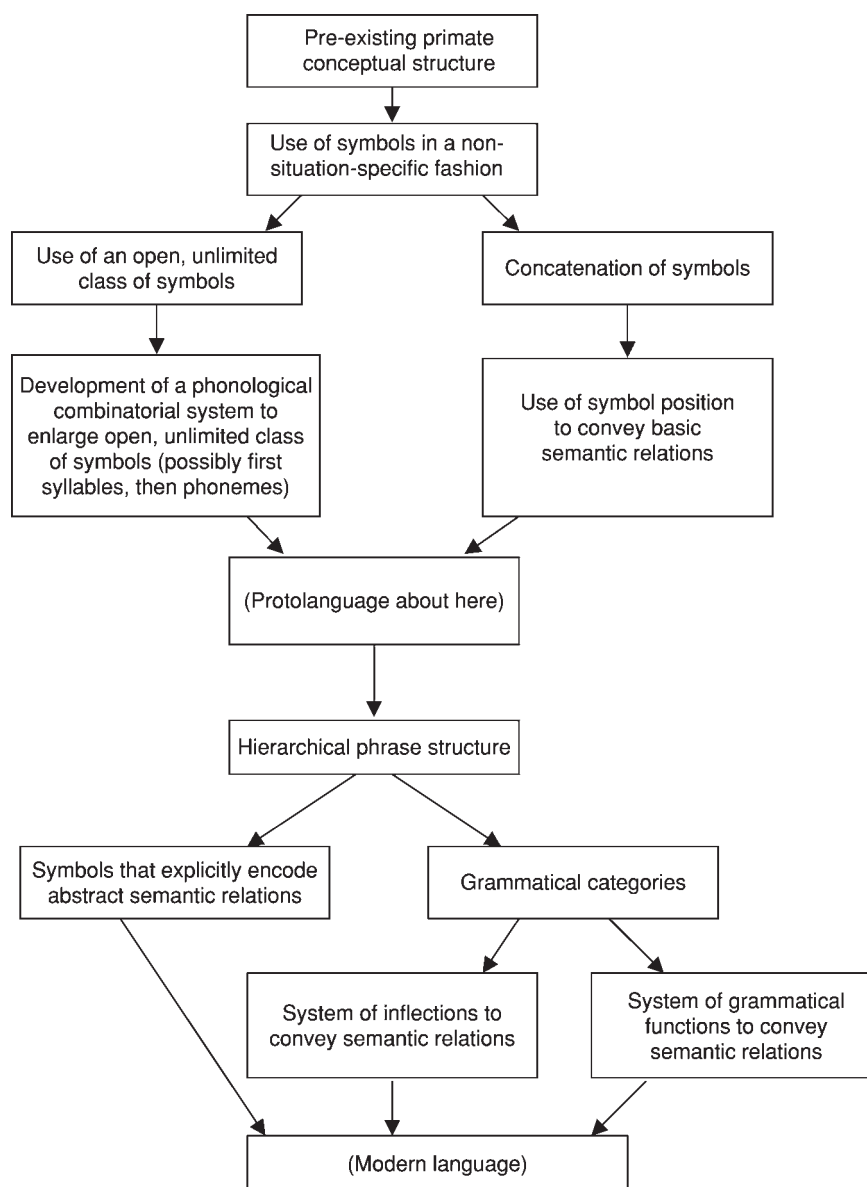

Figure 1 Summary of incremental evolutionary steps (from Jackendoff 2002: 238).

This is different from the combination of sounds just mentioned, in that meaningful symbols are combined to form larger utterances whose meanings are a function of the meanings of the symbols used. In ‘proto-phonology,’ in contrast, meaningless symbols are combined to form meaningful ones.

Concatenating symbols opens up many opportunities for enhancing expressive power and precision. Two important classes of innovations are orthogonal: using the linear order of concatenated symbols to express relations between them, and introducing new sorts of vocabulary item that convey relations explicitly. On this view, the former is a stage on the way to Bickerton’s protolanguage, while the latter

(discussed below) is a stage later than protolanguage on the way to modern language.

With just symbol concatenation, interpreting particular utterances depends very much on contextual inference. Pinker and Bloom (1990) suggest that this means that using principles of word order would be communicatively adaptive. Some principles of word order will narrow down the range of possibilities and lead to a system roughly equivalent to Bickerton’s protolanguage.

An important step in moving from protolanguage to modern language is to develop the means to represent relations not just between words but also between phrases. In a sentence such as *the careless boy*

lost his brother's apple, it is the entire phrase *the careless boy* that enters into a semantic relation with the verb *lost*. This collection of words functions as an elaborated version of the single word *boy*, the head of the phrase. More generally, a noun phrase is an elaborated version of a noun, an adjective phrase is an elaboration of an adjective and so on.

When headed phrases appear, then principles of word order can be elaborated into principles of phrase order. This means that the messages that can be conveyed are much more complex: not just *dog chase mouse*, for example, but also [*big dog with floppy ears and long scraggly tail*] *chase* [*little frightened mouse*]. It also makes possible hierarchical embedding such as [*the dog [that bit the cat [that chased the rat]]*]. This hierarchical embedding is one of the hallmarks of modern language but it is neither simple nor inevitable, even in a generative representation. It does not occur so relentlessly in phonological structure, for example.

This potential complexity raises new problems of communicability. With only three words in a sentence, the relations among them can be conveyed by simple word order plus pragmatics. But when sentences are longer and grouped into phrases, it becomes much more important to make phrase boundaries and the semantic relations among words explicit to the hearer. Language needs further devices than linear order and intonation in order to make semantic relations explicit.

One way to encode semantic relations among words and phrases is to invent words that express them. Relational words are pointless at the one-word stage but are useful once we have multiple-symbol utterances. The next step is the development of grammatical categories, and Jackendoff makes some suggestions about how the distinction between nouns and verbs might have arisen.

Two more changes are needed to move from this point to modern language: the development of morphology and the remaining aspects of syntax. Bickerton and many other linguists treat these as an integrated whole at the core of grammar, but Jackendoff suggests that we might see phrasal syntax and morphosyntax as independently evolved systems, each built on top of the system of protolanguage, each refining communication through its own expressive techniques.

On this speculative picture, then, modern language evolved from primate calls in a number of stages, each step having its own advantages over the step before. This suggests not only that the evolution of language can be seen as happening in a number of discrete steps but also that the syntactic component itself can be further broken down and that syntax itself may have

developed in a series of discrete steps. This leaves open the important question of which of these steps require biological evolution and which could be the consequence of cultural innovation.

Conclusion

Some linguists are reluctant to discuss a topic where the data is so remote. But the data of 'everyday' linguistics is also remote in that it is buried in the minds of language users at a level not accessible to consciousness. Recent work means that we now have a fuller understanding of evolution in general and linguists have been working on formulating and testing clearly stated hypotheses on the evolution of language, including the evolution of syntax. Continuing developments in the study of language and syntax have also helped linguists make significant progress in our attempt to understand the nature of syntax and language and how they evolved. While there is as yet no general consensus, there is a clear sense of an emerging interdisciplinary research program concerned with the evolution of language in general and with the evolution of syntax in particular.

Existence

B Caplan, University of Manitoba, Winnipeg, Canada

© 2006 Elsevier Ltd. All rights reserved.

What Existence Is

Existence is the property that is attributed to Uma Thurman in

- (1) Uma Thurman exists.

Perhaps existence is also attributed to some object in

- (2) There is an even prime.

There is a connection between existence and (objectual) quantification: what exists is exactly what our quantifiers quantify over, when our quantifiers are unrestricted. Sometimes our quantifiers are restricted so that they quantify over only some of the things that exist. For example, in

- (3) All the bottles of beer are in the fridge.

the quantifier "all the bottles of beer" is naturally interpreted so that it doesn't quantify over **all** of the bottles of beer in existence. But what exists is

not limited to what our quantifiers quantify over when they are restricted in one way or another. (In various free logics, variables need not be interpreted so as to have as values objects that exist. Sometimes a special predicate is introduced for 'exists' in these logics. Existence is not tied to quantification in these logics, although it might be tied to the special predicate.)

It seems that existence is a property that everything has: namely, the property *existing* or *being existent*. But various philosophers deny this for various reasons: some deny that existence is a property; others accept that existence is a property but deny that any objects have it (because only properties do); and still others accept that existence is a property but deny that all objects have it (because only some do).

The Hume-Kant View

The Scottish philosopher David Hume (1711–1776) and the German philosopher Immanuel Kant (1724–1804) denied that existence is a property. (It is often said that existence is not a predicate. This is at best a confused way of denying that existence is a property.) Let us call the view that existence is not a property the *Hume-Kant view*. One reason for holding the Hume-Kant view is that existence is supposedly not a property but rather a precondition for having properties. After all, how could something have any properties if it did not exist? But it is hard to see what a precondition is if it is not a property. For example, being human might be a precondition for being a movie star; and *being human* is a property.

Another reason for holding the Hume-Kant view is that to say that something has a property F and exists is supposedly not to say anything more than that something has F. For example,

- (4) Uma is a movie star and exists.

supposedly doesn't say anything more than

- (5) Uma is a movie star.

But if this is a good reason to deny that existence is a property, then it is also a good reason to deny that *being self-identical* or *being either round or not round* is a property. For if (4) doesn't say anything more than (5), then

- (6) Uma is a movie star and is self-identical.

and

- (7) Uma is a movie star and is either round or not round.

don't say anything more than (5) either. But it seems that *being self-identical* and *being either round or not*

round are perfectly respectable properties. For example, *being round* is a perfectly respectable property. And if negations and disjunctions of perfectly respectable properties are themselves perfectly respectable properties, then *being either round or not round* is also a perfectly respectable property.

The Frege-Russell View

Some philosophers who accept that existence is a property deny that everything has it, because they think that no *objects* have it; rather, they think that only *properties* have it. On this view, *existence* is not a (first-level) property of objects; rather, it is a (higher-level) property of properties. In particular, it is the property *being instantiated*. This is a view that was held by the German mathematician and philosopher Gottlob Frege (1848–1925) and, at least at one time, by the British philosopher Bertrand Russell (1872–1970). Let's call this view the *Frege-Russell view*.

One reason for holding the Frege-Russell view is that if existence were a property of objects, then it would not be possible to be mistaken in ascribing that property to an object. (By contrast, one can attribute the property *being instantiated* to the property *being a golden mountain*, say, even if that property is not instantiated.) But if this is a good reason to deny that existence is a property of objects, then it is also a good reason to deny that *being self-identical* or *being either round or not round* is a property of objects. For it is not possible to be mistaken in ascribing those properties to an object either. And yet they are perfectly respectable properties of objects.

Another reason for holding the Frege-Russell view comes from the problem of negative existentials. A *negative existential* is a sentence like

- (8) The golden mountain doesn't exist.

which seems to say of some object that it doesn't exist. For example, (8) seems to say, of the object that "the golden mountain" refers to, that it doesn't exist. Either "the golden mountain" refers to something or it doesn't. On the one hand, if "the golden mountain" doesn't refer to anything, then it seems that (8) doesn't say anything about anything. On the other hand, if "the golden mountain" does refer to something, then it seems that it must refer to something that exists, in which case (8) says, of something that does exist, that it doesn't exist. Either way, it seems that (8) can't be true. But (8) seems true; hence the problem.

The Frege-Russell view offers a straightforward solution to the problem of negative existentials. On the Frege-Russell view, (8) says, of the property *being the golden mountain*, that it does not have the

property *being instantiated*. And it is true that the property *being the golden mountain* does not have the property *being instantiated*. So, on the Frege-Russell view, (8) is true, as desired. (Russell's treatment of definite descriptions like "the golden mountain" is actually more complicated. (see **Descriptions, Definite and Indefinite: Philosophical Aspects**). One might worry that even if Russell's treatment solved the problem of negative existentials for sentences like (8), it wouldn't solve the problem of negative existentials for sentences like

(9) Santa Claus doesn't exist.

which contain names rather than definite descriptions (see **Proper Names: Philosophical Aspects**).

One problem with the Frege-Russell view is that (8) doesn't seem to say the same thing as

(10) The property *being the golden mountain* doesn't have the property *being instantiated*.

Similarly,

(11) If the golden mountain were to exist and if cows were to fly, then just as they would have the property *being able to fly*, it would have the property *being golden*.

seems true, and it doesn't seem to say the same thing as

(12) If the property *being the golden mountain* were to have the property *being instantiated* and if cows were to fly, then just as they would have the property *being able to fly*, it would be instantiated by something that has the property *being golden*.

Another problem with the Frege-Russell view is that the property *being instantiated* doesn't seem to be fundamental in the right sort of way. It seems that facts about which properties have the property *being instantiated* depend on quantificational facts. For example, it seems that the property *being a movie star* has the property *being instantiated* only because some object (Uma, say) instantiates the property *being a movie star*. But it seems that objects (Uma, say) can instantiate properties (*being a movie star*, say) only if they exist. So if it is to be instantiated, then the property *being instantiated* seems to require that some objects exist and hence that, contrary to the Frege-Russell view, existence be a property that at least some objects have.

The Meinong-Russell View

Some philosophers who accept that existence is a property deny that everything has it, because they think that some, but not all, objects have it. At one

time, Russell thought that there is a broad ontological property that everything has; but he thought that this property is *being* (or *subsisting*), not *existing*. On this view, the golden mountain, the round square, numbers, sets, tables, and chairs have being; but only tables and chairs (and other objects that are located in space and time) exist. The Austrian philosopher Alexius Meinong (1853–1920) held a similar view. He thought that there is a broad ontological property that everything has; but he thought that this property is *being an object*, not *being* or *existing*. On this view, the golden mountain, the round square, numbers, sets, tables, and chairs are objects; but of these, only numbers, sets, tables, and chairs have being. (And only tables, chairs, and other objects that are located in space and time exist.) Let's call this – the view that although there is a broad ontological property that everything has, only some objects exist – the *Meinong-Russell view*.

One reason for holding the Meinong-Russell view is that it offers a straightforward solution to the problem of negative existentials. On the Meinong-Russell view, (8) says, of the object "the golden mountain" refers to, that it doesn't exist, and "the golden mountain" refers to an object that doesn't exist. So, on the Meinong-Russell view, (8) is true, as desired.

But the Meinong-Russell view doesn't solve parallel problems. A *negative subsistential* is a sentence like

(13) The golden mountain has no being.

that seems to say of some object that it has no being. Those who distinguish being and existence sometimes say that "there is" has to do with being, not existence. On this view,

(14) There is no golden mountain.

is also a negative subsistential. And a *negative objectual* is a sentence like

(15) The golden mountain isn't an object.

or

(16) No object is the golden mountain.

that seems to say of some object that it isn't an object. Speakers who have the intuition that (8) is true might also have the intuition that (13)–(16) are true. And if a solution to the problem of negative existentials should respect speakers' intuition that (8) is true, then one might think that a solution to the problem of negative subsistentials or negative objectuals should similarly respect speakers' intuition about (13)–(16). But on the Meinong-Russell view, (13) and (14) or at least (15) and (16) are false, because "the golden mountain" refers to an object that has being or at least is an object. (This argument might work best against those who say that (8) is false but (14) is true.) Solving the problem of negative existentials only at the cost of not solving the problem of

negative subsistentials or the problem of negative objectuals doesn't seem like much of a benefit. In addition, many dislike the Meinong-Russell view because, by saying that existence is what Russell (1903) once called "the prerogative of some only amongst beings," the view offends what Russell (1919) later described as "a robust sense of reality."

If one rejects the Hume-Kant view, the Frege-Russell view, and the Meinong-Russell view, one is left with the view that existence is a property that everything has. Although there is much to commend this view, those who hold it still have to solve the problem of negative existentials. This suggests that a solution to that problem will not come from views about existence. And once one had a solution to the problem of negative existentials (whatever that solution is and wherever it comes from), it seems that there would be little to prevent one from holding the view that existence is a property that everything has.

Expression Meaning versus Utterance/Speaker Meaning

A Bezuidenhout, University of South Carolina, Columbia, SC, USA

© 2006 Elsevier Ltd. All rights reserved.

When Mrs. Malaprop in Richard Sheridan's play *The Rivals* says to her niece Lydia Languish "don't attempt to extirpate yourself from the matter," she

means to say that her niece should not attempt to *extricate* herself from the matter. But that is not what 'extirpate' means in English (at least, it is not a meaning one would find listed under 'extirpate' in a good dictionary of English usage). Malapropisms of this sort are one way in which expression meaning (i.e., word or sentence meaning) can come apart from speaker meaning. Mrs. Malaprop has a

mistaken belief about what the words she is using mean in the language she is using. Slips of the tongue (e.g., saying 'pig vat' instead of 'big fat') represent another way in which expression and speaker meaning can come apart.

Gricean conversational implicatures represent another, much larger, class of cases in which these two kinds of meaning come apart. These are cases in which the speaker engages in some form of indirection, where, typically, the main conversational point is something implicitly communicated rather than explicitly expressed. In such cases, the speaker's words mean one thing, but the speaker is trying to convey another meaning, either in addition to the literal expression meaning or in place of it. An example of the former sort is when Mary replies to Peter's offer to take her to the movies that evening that she will be studying for an exam then. Mary has explicitly said that she will be studying, but has implicitly communicated that she is refusing Peter's invitation. Here both the explicit statement and the implicit refusal are intentionally communicated. The statement is intended to give Mary's reason for her refusal. An example of the latter sort is when Mary responds to Peter's refusal to help her when she is in need by saying 'You're a fine friend!' Here she is implicitly communicating that Peter is *not* a good friend. Her words 'fine friend' are being used sarcastically, and she does not intend to communicate what her words literally mean.

It should be mentioned that there are philosophers who think that even what is explicitly said (as opposed to implicitly communicated) can come apart from literal sentence meaning. These are cases where literal expression meaning must be pragmatically narrowed or broadened in order to arrive at what is explicitly communicated. Thus, when Mary says to the waiter at the restaurant that he should take her steak back because it is raw, she doesn't mean to say the steak is literally uncooked, but that it is too undercooked for her taste – a case of pragmatic broadening. Or when Mary tells her son that he is not going to die when he comes crying to her with a cut on his finger, she means to say that he is not going to die from that cut, not that he is never going to die – a case of pragmatic narrowing (see **Pragmatic Determinants of What Is Said**).

For some, utterance meaning is just a variety of speaker meaning. It is the meaning an expression has as used by a speaker in some conversational context. The hearer arrives at an understanding of utterance meaning by combining literal expression meaning with other contextually available information, including information about the speaker's communicative intentions. However, at least some

philosophers of language and linguists wish to draw a contrast between utterance and speaker meaning. Levinson (1987, 1995, 2000) has argued for three levels of meaning. There is expression meaning, utterance meaning, and speaker meaning. Utterance meanings belong to a system of default meanings associated with certain expression types. These default meanings are distinct from literally encoded expression meanings. However, when a speaker utters an expression of this type in a normal context, she will have conveyed the default meaning, unless she either explicitly or implicitly cancels this meaning. Levinson identifies these default meanings with the class of conversational implicatures that Grice called generalized conversational implicatures. For instance, when Peter accuses Mary of having eaten all the cookies and Mary replies that she has eaten some of the cookies, she explicitly says that she has eaten some and possibly all of the cookies, she implicates in a generalized way that she has not eaten all of the cookies, and she implicates in a particularized way that she is not the guilty party. These three meanings correspond to Levinson's three levels of sentence, utterance, and speaker meaning, respectively.

The distinction between expression and speaker meaning has been invoked in many philosophical debates as a way of avoiding the postulation of multiple meanings for a single expression type. One well-known instance is Kripke's (1977) appeal to a distinction between speaker's reference and semantic reference of definite descriptions. Kripke appealed to this distinction in order to deny the semantic significance of what Donnellan (1966) called the referential use of such descriptions. Suppose Mary uses the description 'the man in the corner drinking a Martini,' intending to refer to Peter, but in fact Peter is drinking water, not Martini. Kripke argues that the so-called referential use of the description can be accounted for by appeal to what Mary meant to convey by the use of that expression, whereas what she actually said is determined by giving a Russellian analysis of the description. Since there is no unique Martini drinker in the corner (since, let us suppose, there is no Martini drinker there), what Mary has said is false, although what she meant to convey (her speaker meaning) may very well have been true.

There are differing views as to the relative priority of expression and speaker meaning. Some philosophers, such as Strawson (1950), have argued that it is not words and sentences by themselves that refer or express propositions. Rather, it is speakers who refer or express propositions by their uses of words and sentences, respectively. Salmon (2004) calls this the speech-act-centered conception of semantics and contrasts it with the view he favors, namely the

expression-centered conception. According to the latter conception, words and sentences have their semantic properties intrinsically, in the sense that one can talk about the referential and truth-conditional content of expressions without any knowledge of or appeal to the communicative intentions of users of those expressions.

Although defenders of the speech-act-centered conception are committed to denying that expressions have referential or truth-conditional content independently of speakers' communicative intentions, their view is compatible with the claim that expression types have aspects of meaning that are context invariant. These would correspond to Fregean 'senses' or 'modes-of-presentation' or (for demonstratives and indexicals) to Kaplanian 'characters.' Such nonreferential or nontruth-conditional aspects of meaning may be intrinsic in Salmon's sense. In other words, such meaning would be a property of expression types, independently of the intentions of the users of those expression types.

Some philosophers of language have denied the idea of intrinsic expression meaning independent of speaker meaning. For instance, Grice (1957) argued that expression meaning is reducible to speaker meaning. Grice was interested in nonnatural meaning (Meaning_{NN}), as opposed to the sort of natural meaning that a sign may have in virtue of naturally signaling or indicating some state of affairs. He argued that an utterance's nonnaturally meaning that *p* is simply a matter of a speaker's uttering an expression with a certain communicative intention. This would be a sort of 'one-off' meaning for that expression. However, that speaker may be disposed to utter an expression of this type whenever he wishes to convey a certain meaning. Thus, he might develop a habit of using that expression type that way. If this usage were then to spread to other members of his community, it would become a standardized usage, and that expression type would come to have a stable meaning independent of the intentions of any one speaker. But such a meaning would not be independent of the linguistic activities of the users of the expression type in general.

Another way that defenders of a speech-act-centered conception have challenged the idea of intrinsic

expression meaning is to argue with Searle (1983) that all meaning is relative to a nonintentional Background. A sentence only has truth-conditions relative to some assumed Background. This Background can never be made fully explicit, because at bottom it consists in a set of abilities, practices, and ways of acting that are nonintentional. Although Searle, unlike Grice, is not suggesting that expression meaning depends ultimately on the communicative intentions of speakers, he is arguing that expression meaning depends on a certain sort of human activity, and so this conception is antithetical to the idea of intrinsic expression meaning.

Expressive Power of Language

D Gil, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

The expressive power of a language is its ability to convey meanings of various kinds. Most often, the term is used in comparative or contrastive contexts, for example, to claim that one language is of greater expressive power than another in a certain semantic domain.

At one time, it was believed that the classical languages of Western civilization enjoyed much greater expressive power than the so-called primitive languages of Africa, Asia, Oceania, and the Americas. However, when linguists began familiarizing themselves with more distant and exotic languages, it became clear that they were anything but impoverished in their expressive power. Today, it is generally accepted that all languages are endowed with expressive power of similar order of magnitude.

Nevertheless, within particular domains, languages may still vary substantially with respect to their expressive power. Perhaps the most celebrated example of crosslinguistic variation in expressive power, the Eskimos' purported plethora of 'snow words,' has recently been called into question; however, numerous other examples are empirically well-supported. In order to compare the expressive power of languages, it is necessary to consider the forms that may bear meanings, the meanings that may be borne by those forms, and the nature of the form-meaning relationship.

The forms that may bear meanings are linguistic units of various size: morphemes, words, phrases, clauses, sentences, and texts. Alongside these, intonation contours may also be associated with meanings. In addition, smaller, phonological units may bear meanings in what is known as sound-symbolism.

The meanings that are borne by linguistic forms may be broadly characterized as either conceptual or affective. Conceptual meanings are based on the traditional notions of semantics, such as propositional content, modality, and reference, and may be further classified into various semantic domains, including thematic roles, tense/aspect, quantification, kinship terms, color terms, weather terms, and so forth. In contrast, affective meanings involve states such as tension, happiness, arousal, and their like.

The form-meaning relationship, that is to say the association of linguistic forms with their particular meanings, is the basis of the expressive power of language. For any given meaning *M*, the following

three cases may, potentially, be distinguished: (a) *M* is expressible in all languages; (b) *M* is expressible in no languages; and (c) *M* is expressible in some but not all languages. However, the above taxonomy faces a number of serious problems.

One difficulty is empirical: without access to each and every one of the world's thousands of languages, it is an extremely risky proposition to make any universal generalizations to the effect that a certain meaning may be expressible in all languages, or in none. In lieu of a much larger data base than is currently available, all such claims must therefore be treated as conjectures of various degrees of plausibility.

Another issue pertains specifically to the meanings purportedly expressible in no languages. Some scholars view language as system of societal conventions, and meanings, in particular, as essentially public entities: for such scholars, the concept of an unexpressible meaning is therefore an oxymoron. More generally, by their very definition, meanings expressible in no language can never be referred to, even indirectly, as in expressions such as *the meaning of Mona Lisa's smile*: the very notion of unexpressible meaning is thus paradoxical.

Nevertheless, prophets, poets, and others have reported undergoing mystical experiences beyond the realm of linguistic expression; similar claims are also made by persons who have entered altered states of consciousness, for example, with hallucinogenic drugs. Indeed, the logical positivists maintained that natural languages are incapable of expressing scientific concepts with sufficient precision; this postulate was their motivation for proposing an 'artificial language of science.' More far reaching, cognitive scientists have suggested that the human mind is innately incapable of grasping certain kinds of knowledge; such knowledge would, *a fortiori*, be unexpressible in any language. In view of such claims, it would therefore seem advisable to at least entertain the possibility that there may exist meanings expressible in no languages, in spite of the problems inherent therein.

A further, much-debated issue is that of crosslinguistic synonymy. Some linguists question whether linguistic forms in different languages are ever capable of bearing the exact same meaning. Each and every linguistic form is part of a language system; hence, it is argued, linguistic forms belonging to different language systems can never be equivalent. The issue of crosslinguistic synonymy is of course crucial to the process of translation: if complete crosslinguistic synonymy is not attainable, neither is the 'perfect translation.' Nevertheless, for many purposes, it would seem advantageous to abstract away from

such subtleties, in order to posit crosslinguistic synonymy, when equivalence of meaning, up to a certain point, can be seen to obtain.

A particular problem arises when supposed crosslinguistic synonyms are constructed from linguistic forms of different types, or 'sizes.' Consider, for example, the English expression *boy* and its nearest equivalents in Hebrew, *yeled*, and in Tagalog, *batang lalaki*. Whereas English has a monomorphemic word, Hebrew possesses a bimorphemic word consisting of root *y-l-d* 'child' plus masculine singular inflection *-e-e-*, while Tagalog makes use of two words, *batang* 'child' plus a grammatical linker, and *lalaki* 'male.' It is at least plausible to suggest that the meanings associated with *boy*, *yeled*, and *batang lalaki* reflect their different structures. Specifically, whereas a semantic representation of *boy* might involve a primitive concept Boy, that of *yeled* might be obtained by application of a masculine feature to Child, while that of *batang lalaki* might be constructed compositionally, by modifying Child with Male.

It would therefore seem crucial to distinguish between the different types of linguistic forms that may bear meanings: segments, morphemes, words, phrases, clauses, sentences, texts, intonation contours, and so forth. Specifically, for any meaning M, and any type of linguistic form T, the following three cases may be distinguished: (a) M is expressible by a form of type T in all languages; (b) M is expressible by a form of type T in no languages; and (c) M is expressible by a form of type T in some but not all languages. Following are some examples of each of these three cases.

Taking T to be morpheme, and examining the semantic domain of cardinal numerals, One is possibly expressible by a single morpheme in all languages, whereas One Hundred And Twenty Three is almost certainly expressible by a single morpheme in no languages. In between these two extremes, Eleven is expressible by a single morpheme in English *eleven*, but not in Malay, where *seblas* consists of *se-* 'one' plus *-blas* 'over ten'; while One Hundred Thousand is expressible by a single morpheme in Hindi *laakh*, but not in English.

Letting T stand for word and generalizing the semantic domain to that of quantification, One is possibly expressible by a single word in all languages, whereas At Most Four Or More Than Seven is almost certainly expressible by a single word in no languages. In between, the quantifier No is expressible by a single word in English *no* (as in *no languages*), but not in Hebrew, where it would be paraphrased with a negative polarity marker *af* preceding the noun plus a negation *lo* in construction with the verb; while

Only One is expressible by a single word in Tagalog *iisa*, but not in English.

Taking T to denote clause, simple propositions such as John Came are perhaps expressible by a single clause in all languages, whereas a conditional linking two events such as If John Comes, Bill Will Go most probably cannot be expressed monoclausally in any language. However, propositions involving conjoined participants such as John And Bill Came can be expressed by a single clause in English, *John and Bill came*, but not in the Amerindian Yuman language Maricopa, where its nearest equivalent, *John-f Bill uðaavk vʔaawk*, contains an embedded clause *John-f Bill uðaavk* 'John accompanied Bill.' Conversely, propositions involving indirect causation such as John Caused Bill To Write A Letter can be expressed monoclausally in Hindi, as in *John-ne Bill-se khat likh-waayaa*, making use of a single verb *likhwaayaa* 'write' inflected for indirect causation, but not in English, where, in the nearest equivalent, *John caused Bill to write a letter*, two verbs, *caused* and *write*, head two different clauses.

Letting T represent intonation contour, emphasis is probably expressible via intonation in all languages, while a cardinal numeral such as Seven is almost certainly expressible through intonation in no languages. However, yes/no questions can be formed with intonation in English, but not, allegedly, in Thai, whereas 'a variety of exclamation colorings,' including 'the lack of concern on the part of the speaker for the outcome of his utterance' can be expressed intonationally in Vietnamese, but not in English.

Finally, taking T to denote phonological feature, harshness and aggression are possibly expressible, through sound symbolism, by the feature [obstruent] in all languages, while a cardinal numeral such as Seven is almost certainly expressible with a phonological feature in no languages. However, since the association of phonological features with meanings is based on universal cognitive principles, falling outside the domain of conventionalized and possibly language-specific grammatical rules, there are probably no cases of meanings expressible by phonological features in some but not all languages.

In those cases where a meaning M is expressible by a form of type T in some but not all languages, the availability of M as a meaning of a Type T form may be correlated with various other linguistic properties. Such correlations can be represented as implicational universals of the following form: (a) For any language L, if M is available as a meaning of a Type T form in L, then L has property P; and (b) For any language L, if L has property P, then M is available as a meaning of a Type T form in L. At present, however, not enough is

known about patterns of crosslinguistic variation in expressive power to conclusively support a significant body of such universals. Nevertheless, some work in linguistic typology has pointed towards possible correlations between expressive power and various other linguistic properties.

For example, in phonological typology, it has been suggested that intonation is associated with less expressive power in tonal languages than in their nontonal counterparts. Similarly, in morphological typology, the word is generally endowed with less expressive power in isolating languages than in synthetic ones, and less expressive power in synthetic languages than in polysynthetic ones, such as the Australian language Mayali, in which a single word *gayauganjngunihmiwage* can mean 'the child crawls along eating meat.' Analogously, in syntactic typology, the sentence is generally equipped with less expressive power in English and other European languages than in several Papuan languages of the so-called clause chaining type, in which a single sentence can narrate a series of events that, in most other languages, would require a lengthy sequence of sentences.

While some facts and generalizations about the expressive power of language can be accounted for terms of linguistic typology, others would seem to result from extralinguistic factors, while yet others would appear to be immune to either kind of explanation,

instead reflecting the arbitrariness of language and linguistic structure.

Extensionality and Intensionality

N Oldager, Technical University of Denmark, Lyngby, Denmark

© 2006 Elsevier Ltd. All rights reserved.

A sentence is extensional if its expressions can be substituted with expressions that have the same denotation (reference) without altering the truth value of the sentence. A sentence that is not extensional is intensional. A language is extensional if every sentence of it is extensional. Otherwise, the language is intensional.

The following sentence is then intensional:

George IV wished to know whether Scott was the author of *Waverly*.

As Scott was in fact the author of *Waverly*, 'Scott' and 'the author of *Waverly*' are co-denotational. However, if we substitute one for the other, we get

George IV wished to know whether Scott was Scott,

which, unlike the former, can hardly be taken as true. Because natural language contains intensional sentences, natural language is intensional.

A context in which co-denotational expressions cannot be substituted is known as an indirect context (or oblique, opaque or intensional context), and a context of extensional expressions is a direct context. Sentences involving propositional attitudes, intentions, quotations, temporal designation, and modalities give rise to indirect contexts. Another example of intensionality:

Nine necessarily exceeds seven.

Nine is the number of the planets.

The number of the planets necessarily exceeds seven.

Although the first two sentences are true, the third is not because it is only a contingent astronomical fact

and not a necessary truth that the number of planets exceeds seven – it is possible that there were only seven planets.

Semantical Aspects of Extensionality and Intensionality

Issues concerned with extensionality and intensionality have been cardinal motivations behind the development of important semantical theories. Reducing extensionality and intensionality to technical conditions regarding substitutivity of expressions is accordingly a crude simplification.

Though extensionality and intensionality can be traced as far back as ancient Greek philosophy, the first major contribution to the subject was Gottlob Frege's *Über Sinn und Bedeutung* (Frege, 1892). Note, there are different translations of the title words of this work: *Sinn* is translated as 'sense' but *Bedeutung* is translated as either 'denotation', 'reference', or 'nominatum' ('meaning' has actually been used for both *Sinn* and *Bedeutung*). Following Bertrand Russell and Alonzo Church, *Bedeutung* will be identified with 'denotation'.

Although Frege does not spell it out in detail, he maintains that semantics is compositional, such that the semantics of a sentence is determined by the semantics of its parts. To illustrate his theory, assume, to begin with, that semantics is purely referential, that is, assume that the semantics of an expression is what the expression denotes. This seems plausible; for example,

Paris is beautiful

asserts that what 'Paris' denotes, i.e., the actual capital of France, has the property of being beautiful. It is not the string of symbols 'Paris' or one's idea of Paris, whatever that may be, which is beautiful.

However, things are more complicated than this. There are aspects of natural language semantics that cannot be explained by resorting to the notion of denotation, Frege argues. He illustrates this by the following puzzle. Suppose a and b are names for some objects and that

$$a = b$$

is true, hence the expressions ' a ' and ' b ' have the same denotation.

Frege then recognizes a difference between this identity and an identity such as $a = a$. The latter is trivially true (analytically true), whereas the former may contain useful information. For instance, in a criminal investigation a discovery such as "the burglar is the suspect" could be decisive, whereas "the burglar is the burglar" is useless. The important question is

then: What is the source of the difference between $a = a$ and $a = b$? As semantics is compositional, the difference must be due to a difference between the semantics of the expressions ' a ' and ' b '. But by assumption, ' a ' and ' b ' have the same semantics because they have the same denotation. In other words, referential semantics must be rejected because it cannot explain the difference between the identities.

Frege's famous solution is to acknowledge that ' a ' and ' b ' refer to their denotation in different ways. Consider, for example, the expressions 'morning star' and 'evening star.' Both denote the planet Venus, so *morning star* = *evening star* is true, but they refer to Venus in different ways: One refers to a heavenly object seen in the morning, the other to a heavenly object seen in the evening. Frege says 'morning star' and 'evening star' have different senses. The puzzle about identity can now be solved by noting that $a = a$ and $a = b$ express different senses. Frege was inspired by mathematics when he developed this theory. Consider the two expressions ' $1 + 3$ ' and ' $2 * 2$ '. Both are equal to, i.e., denote, the number 4, however, their way of referring to four differs because the calculations for obtaining the result differ. Hence, the expressions have different senses.

To solve the puzzle, Frege accordingly introduces two semantical concepts, denotation and sense. Each expression – including proper names and sentences – is then assumed to have both a denotation as well as a sense, although he recognizes that exceptions may occur. Frege never precisely described what senses are, but he explained that the sense of an expression contains its mode of presentation (its way of referring), that expressions express their senses, and senses are something we grasp. Moreover, senses are distinguished from ideas (subjective thinking), meaning they are objective. The notion of sense may appear unfamiliar and it may not be clear why it is seminal. However, expressions such as 'morning star' or 'Paris' are signs, and signs are characterized by their ability to refer to something. Sense addresses this fundamental feature – the referential capacity of expressions. So, it is natural to discern between expressions that refer to the same thing.

There is a close relationship between Frege's theory and the earlier definition of extensionality and intensionality. Frege can now provide an explanation for failure of substitutivity in indirect contexts. In indirect contexts we are talking about the senses of the expressions occurring therein. When we say

John believes that the morning star is the evening star

we are not talking about Venus, Frege argues, but about different senses that determine Venus. In

indirect contexts the semantics become the sense. Thus, when we substitute two co-denotational expressions that have different senses in indirect contexts, we obtain different propositions that may have different truth values.

Frege's theory has been challenged by, among others, Bertrand Russell (Russell, 1905). Russell notes that in Frege's theory, a phrase such as "the present Queen of England" denotes an actual woman. It would seem, by parity of form, that a phrase like "the present King of France" also is about, i.e., denotes, an actual individual. However, as an actual King of France does not exist, this sentence does not denote – it merely expresses a sense. Only when sentences are false or nonsense, do we talk about senses, it seems. Russell then presents a rival theory of denotation which, by means of a clever paraphrasing technique, does not resort to Fregean senses. However, it faces other difficulties. For instance, Russell would have to accept that

Ponce de Leon sought the fountain of youth

is either false or nonsense because there did not exist an actual fountain of youth.

There are other semantical theories and notions similar to Frege's. The notion of connotation is similar to sense. Rudolf Carnap (Carnap, 1947) has presented a semantical method in which he distinguishes the notions extension and intension. These are closely related to Frege's notions, in fact, in direct contexts extension and denotation are the same, and so are intension and sense; only in indirect contexts does Carnap distinguish his notions from Frege's. Common to these theories is the distinction between two semantical notions, one more general than the other.

Extensionality and Intensionality in Formal Settings

So far, the investigations have been restricted to natural language; in the following they will be generalized to logic. The underlying idea is to formalize the condition for extensionality (substitutivity of co-denotational expressions). This will allow us to determine whether a logic is extensional or intensional.

In propositional logic, the formula

$$(1) (P \leftrightarrow Q) \rightarrow (R \leftrightarrow R[Q/P])$$

is valid (logically true) for all formulas P , Q , and R , where $R[Q/P]$ is the result of substituting zero or more occurrences of P with Q in R . This result says that equivalent (co-denotational) formulas can be substituted with preservation of truth, hence, that propositional logic is extensional.

In contrast, modal logic is intensional because (1) is not valid in modal logic. We have the following counterexample comprising the necessity operator:

$$(p \leftrightarrow q) \rightarrow (\Box p \leftrightarrow \Box p[q/p]),$$

that is,

$$(p \leftrightarrow q) \rightarrow (\Box p \leftrightarrow \Box q)$$

is not valid, where p and q are atomic propositions. Thus, in modal logic we cannot substitute equivalent formulas, but this is precisely what we want because modal logic formalizes the intensional notion of modality. The example shows that \Box creates an indirect context.

Presenting a general, formal definition of when a logic is extensional is no trivial task. One reason is that the notion of logic is general indeed, meaning there are several, non-equivalent formalizations of the condition for extensionality. Consider first-order predicate logic, which is commonly said to be extensional. If we accept open formulas (formulas in which variable occurrences are not bound, such as $F(x)$), formula (1) is not valid. But this means that we would have to say that predicate logic is intensional. However, (1) is not the only formalization of the condition for extensionality for predicate logic. As an alternative formalization, we have:

$$(2) \text{ If } P \leftrightarrow Q \text{ is valid then } R \leftrightarrow R[Q/P] \text{ is valid.}$$

The difference between this formalization and (1) is that (2) is formulated in metalanguage. As (2) holds, it says that predicate logic is extensional in terms of metalogical formalization. Unfortunately, we cannot adopt (2) as a general formalization of extensionality because modal logic also satisfies (2), meaning it would become extensional too. A possible solution is to discard open formulas in predicate logic and accept (1) as a formalization of extensionality. However, other solutions might be preferred. It has been suggested, e.g., by Ruth Barcan Marcus (Marcus, 1960), that there are several principles (definitions) of extensionality, and hence also several principles of intensionality. This reveals subtleties in the distinction between extensionality and intensionality.

Because of their imprecise nature, intensional notions such as sense have been deemed opaque. However, the last 50 years of developments in non-classical logic, in particular the development of possible-world semantics by such people as Saul Kripke and Richard Montague (1970), have shown that a significant part of intensional notions can be formulated in precise (mathematical) settings. See Gamut (Gamut, 1991) for an introduction and Fitting and Mendelsohn (Fitting and Mendelsohn, 1998) for newer developments in possible-world semantics.

Externalism about Content

J Brown, Bristol University, Bristol, UK

© 2006 Elsevier Ltd. All rights reserved.

The Thesis of Externalism

Externalism is a thesis in the philosophy of mind about thought content, i.e., what is believed, desired, hoped, feared, etc. We can distinguish externalism and its opposite, internalism, by contrasting relational properties such as the property of being taller than the Eiffel Tower, and intrinsic properties, such as the property of being made of iron. Externalism treats the property of having a certain thought content as a relational property, whereas internalism treats it as an intrinsic property.

As an example, let Oscar and Twin Oscar share all their intrinsic properties: they are molecule-for-molecule physical duplicates; they share all the same dispositions to behave, where behavior is construed as bodily movement non-intentionally described; and they share all the same ‘narrow’ functional properties, i.e., functional properties defined in terms of causal relations within the body. Externalism claims that Oscar and Twin Oscar may have different thought contents if they are in different environments. Internalism claims that Oscar and Twin Oscar have the same thought contents. Thus we may understand the dispute between externalism and internalism in terms of supervenience. Internalism claims, while externalism denies, that thought content supervenes on the properties that duplicates like Oscar and Twin Oscar share.

Externalism has important consequences for the philosophical debate about the relation of mind and body. Externalism is incompatible with the behaviorist claim that talk of mental states can be reduced to talk of dispositions to behave, where behavior is

construed as bodily movement non-intentionally described. Further, externalism is incompatible with the reduction of types of mental state either to types of brain state, or to narrow functional types. Externalism rejects the Cartesian supposition that a normally embodied person and an always envatted brain (i.e., one not connected to a real body in a real world) could have all the same mental states while being in radically different environments. (Notice that externalism and internalism should not be understood as disputing the uncontroversial truth that a subject’s environment causally affects what she thinks. For instance, an internalist who claims that types of mental state are identical to types of brain state may agree that a subject’s environment causally affects what types of brain state he is in, and so what types of mental state he is in.)

Arguments for and against Externalism

Natural Kind Terms

Putnam’s classic twin earth argument for externalism asks us to imagine that there is a far away planet, Twin Earth, that is a physical duplicate of Earth and that contains duplicates of all Earthians. The only difference between the planets is that whereas, on Earth, the stuff that flows in rivers and falls as rain has chemical composition H_2O , on Twin Earth, the stuff that flows in rivers and falls as rain is an identical seeming stuff that has a different chemical composition, abbreviated XYZ. Consider an Earthian, Oscar, in 1750 when the chemical composition of water was not yet known. Putnam claims that when Oscar sincerely says, “Water is wet,” the term ‘water’ and the concept it expresses refers to all and only H_2O , so that the truth value of Oscar’s utterance and thought turns on the properties of

H₂O. By contrast, Putnam claims that when Oscar's Twin Earthian twin, Twin Oscar, makes the same utterance, the term 'water' and the concept it expresses refers to all and only XYZ, so that the truth value of Twin Oscar's utterance and thought turns on the properties of XYZ. Given that it's an assumption of the thought experiment that Oscar and Twin Oscar are physical duplicates, the fact that their utterances and thoughts are about different substances and have different truth conditions seems to support the externalist claim that a subject's thought contents are partly individuated by the sorts of substances present in his environment.

As initially set-up, the thought experiment suffers from the fact that since humans are largely made out of water, Oscar and Twin Oscar cannot be physical duplicates. However, the thought experiment can easily be reformulated to overcome this objection, by using a term for a 'natural kind' that is not part of the physical constitution of humans. The thought experiment exploits the idea that we intend some of our terms to refer to natural kinds that are naturally demarcated by their fundamental properties, and it is the job of science to discover those properties. On this view, an item could appear superficially just like instances of a certain natural kind and yet not be of that natural kind if it lacks the relevant fundamental properties (e.g., fool's gold). Further, an item could be of a certain natural kind even without possessing its characteristic appearance if it has the fundamental properties definitive of that kind (e.g., an albino tiger). If we intend 'water' to refer to such a natural kind, then XYZ is not included in the reference of our term for, although it looks and behaves like H₂O, XYZ is stipulated to differ in its fundamental chemistry.

One could object to Putnam's Twin Earth argument by rejecting some of the assumptions on which it lies: for example, that there are natural kinds, that some of our non-technical terms aim to refer to such kinds, and that if a substance like XYZ were discovered it would be incorrect to regard it as of the same natural kind as H₂O. Even if all these assumptions are granted, one could further object to the argument that one can accommodate the idea that Oscar's and Twin Oscar's thoughts refer to different substances without granting the externalist claim that their thought contents are partly individuated by the substances in their respective environments. Suppose that each would explicate the meaning of 'water' as "the watery stuff around here." On this explication, since the watery stuff in Oscar's environment is H₂O, in his mouth, 'water' would refer to H₂O. By contrast, since the watery stuff in Twin Oscar's

environment is XYZ, 'water' in Twin Oscar's mouth would refer to XYZ. In this way, someone could hope to explain how Oscar's and Twin Oscar's utterances and thoughts refer to different substances within a view that treats their reference as being determined by a common rule, or 'character' in Kaplan's sense. Such a 'two-dimensionalist' view could arguably be used to support an internalist account of Putnam's Twin Earth story.

Indexicals

A second argument for externalism concerns reference to particular objects, rather than natural kinds. Suppose that a subject sees a blue lamp and says, "That lamp is broken." His utterance and the thought it expresses refer to the lamp he sees, and their truth value turns on the properties of that object. An internalist could suggest that the content of the demonstrative expression and the corresponding thought constituent is given by a certain condition such that the demonstrative expression and thought constituent refer to an object if and only if it meets that condition, say the condition of being the unique blue lamp (on some interpretations, this condition is an example of a Fregean 'sense'). On this view, in a counterfactual condition in which the subject is in the same intrinsic state but looking at a duplicate lamp he would have the same thought content. However, there are a number of objections to the suggested internalist understanding of demonstrative reference. First, it is hard to specify a condition that both uniquely picks out the intuitive referent and that is plausibly available to any subject capable of making or understanding demonstrative reference. Second, understanding the demonstrative expression arguably only requires latching onto the right object, regardless of how one conceives of it. As a result of these difficulties, externalists suggest that the object referred to partly specifies the content of the demonstrative expression and thought constituent, so that if the subject had instead been looking at a duplicate lamp the content of his thought and utterance would have been different. This alternative view supports the externalist claim that a subject's thoughts are partly individuated by the objects in his environment. An internalist could try to avoid this conclusion by exploiting a two-dimensionalist framework in a way analogous to the potential two-dimensionalist reply to Putnam's argument.

Burge and Linguistic Practice

A third argument for externalism, forwarded by Burge, aims to show that a subject's thought contents are partly individuated by the linguistic practices of

his community. Burge's argument concerns a subject, Alf, an ordinary member of the English-speaking community and arthritis sufferer who complains to his doctor, "I fear my arthritis has spread to my thigh." This attitude indicates that Alf incompletely understands arthritis for, by definition, 'arthritis' applies only to problems of the joints. Despite this, Burge argues that Alf has the concept arthritis and that, by his utterance, he expresses the fear that his arthritis has spread to his thigh. Burge supports this interpretation by saying that it would be natural to report Alf's thoughts in this way, despite his incomplete understanding.

Now consider a duplicate of Alf, Twin Alf, who has been brought up in a counterfactual linguistic community in which 'arthritis' is instead defined to apply to rheumatoid ailments of the joints and thighs. In the counterfactual situation, the term 'arthritis' does not express the English concept arthritis. Like Alf, Twin Alf complains to his doctor, "I fear that my arthritis has spread to my thigh." Burge argues that, in the counterfactual situation, Twin Alf lacks the concept arthritis and thus expresses a different thought by his utterance than Alf does. This claim is supported both by the way Twin Alf would explicate 'arthritis' and by how experts in his community would explicate the term. Unlike Putnam's Twin Earth argument, Burge's argument can use a variety of terms and needn't use natural kind terms.

Burge's argument relies on the idea that one may have a concept that one incompletely understands. So, an internalist might object to Burge's argument by rejecting this assumption. In reply, an externalist may point out that the notion that a subject may incompletely understand a concept she possesses is supported by our ordinary practice of attitude ascription in which we routinely ascribe concepts to subjects even despite their incomplete understanding of the relevant term, and regard them as sharing beliefs with others who fully understand the term. Further, it seems supported by Alf's own understanding of the situation. Suppose that the doctor reassures Alf, saying that, by definition, arthritis cannot occur in thighs. It seems likely that Alf would defer to the doctor about the application of 'arthritis,' and regard his earlier fear as false. But, this response suggests that it is the public concept arthritis that figures in his belief, not some idiosyncratic concept defined by his own views.

Accounts of Content

As well as the particular arguments for externalism detailed above, a more general motivation arises from

"naturalistic accounts of content." Such accounts start from the thought that content is not a fundamental feature of the world but can be accounted for in terms of other non-intentional features of the world. On the "causal account," what it is for a state of a system to have a certain content is for it to bear certain kinds of causal relations to other items. On the "teleofunctional account," a state of a system has a certain content if and only if it has a certain evolutionary history. On both of these leading naturalistic accounts, what it is for a state of a system to have a certain content involves its relational properties to items outside that system.

Externalism's Consequences

In addition to its consequences for the mind-body debate (detailed above), externalism has been claimed to have controversial consequences in epistemology and philosophy of mind, in particular for knowledge of one's own mind, knowledge of the world, and the explanation of action. If one's thoughts are partly individuated by the environment, it seems hard for one to know what one thinks just by introspection and without first investigating the environment. Further, if what one thinks depends on the kind of environment one is in, then it may seem that were one to know what one thinks introspectively one could use that knowledge to gain knowledge of the environment without first investigating it! Externalism may also seem to conflict with the plausible intuition that what one thinks causally explains one's actions, given the metaphysical assumption that causal powers depend on intrinsic and not relational properties.

Fictional Discourse: Philosophical Aspects

D Davies, McGill University, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Fictional discourse is among the most superficially unproblematic yet philosophically puzzling of linguistic phenomena. We usually have little difficulty distinguishing fictional from nonfictional writings. We easily make sense of what is set out within the pages of fictions, and readily agree that Pegasus is a winged horse and not a one-legged donkey. Nor are we unreflectively perplexed by the feelings aroused in us by fictions. But each of these issues – the nature of fictional discourse, its meaningfulness, our ability to determine what is true in a fiction, and our capacity to be moved by it – has engendered heated philosophical debate that shows no sign of abating. While some of these issues concern only philosophers of art and literature, others bear on wider issues in ontology and the philosophy of language.

The Nature of Fictional Discourse

As will become apparent, a number of significantly different linguistic phenomena might be classified as forms of fictional discourse, but the core phenomenon is the use of language in fictional narratives such as the Sherlock Holmes stories. The fictionality of such narratives cannot be simply a matter of whether they portray actual happenings and actual agents, for works of fiction seem to contain numerous truths about the real world – e.g., true statements about the geography of Victorian London in Dickens's *Bleak house*. Furthermore, some paradigmatic works of nonfiction, such as medieval texts on alchemy, are largely false. Nor can the style of narration or the use of 'literary' techniques serve as a criterion of fictionality; there are non-fictional works that make free use of the narrative structures and stylistic devices typical of fiction (e.g. Mailer's *The executioner's song*), and celebrated works of fiction that adopt the style of nonfictional genres of writing (e.g. the 'academic' style of Nabokov's *Pale fire*).

The fictionality of a narrative may therefore depend upon **how it functions**, or **how it was designed to function** – either the function conferred upon it by its users (e.g., Walton, 1990), or its author's intention that it function, or be used, in a certain way. Philosophers attracted by the latter analysis have drawn upon the more general notion of a speech act, that is, an action performed by using language (verbal or nonverbal) in a certain way (Searle, 1975). The paradigm speech act is assertion, and Searle has maintained that fiction results when an agent **pretends** to assert what is stated by the sentences that make up a narrative. Given that there seem to be pretended assertions that do not result in fictions – e.g. a satirist's mimicking of a politician, Currie (1990) proposed that fiction results from the genuine performance of a speech act, but one that differs from assertion in that, whereas the latter requires that the speaker intend her audience to **believe** what she states, the author of a fictive utterance intends that her audience **make believe** what is narrated (see also Lamarque, 1996). To understand a work of fiction, then, is to grasp what it is that, as reader, one is intended to make believe.

Truth in a Fiction

If this is on the right track, what reading strategies should one adopt to determine what one is required to make believe to count as understanding what is 'true in a story'? Not everything explicitly affirmed by the narrator of a story can be true in the story, for there are deceived, or deceiving, or ironic narrators. Nor should we restrict what is true in a story to what is explicitly affirmed by a trusted narrator, for sometimes, as in ordinary discourse, we take a narrator to be communicating more by her words than is strictly stated. We also assume, in our reading, that many things are true in a story although they are neither explicit nor implicit in the trustworthy affirmations of the narrator. We must therefore explain how we determine the unspecified background of general propositions that are nonexplicitly true in a given story. One strategy, here, appeals to what philosophers term

“possible worlds” – roughly speaking, alternative ways the actual world might have been (Lewis, 1983): what is true in a (fictional) story *N* is decided by reference to possible worlds in which those things that are explicitly or implicitly true in the text of *N* are actually true. The task, then, is to pick out a particular group of such possible worlds as the ones that determine what else is true in the story.

A general problem for any such account of fictional truth, however, is that it cannot deal with stories in which **inconsistent** truths obtain – for example, certain sorts of time-travel stories – since possible worlds must themselves be **consistent** in order to be possible. To resolve this problem, Currie has proposed an analysis not in terms of possible worlds in which a given set of beliefs is true, but, rather, in terms of belief-sets themselves. He maintained that, in reading fictional narratives, we make believe that we are being informed about the events in the story by a reliable source, the so-called fictional author of the story. It is by reference to the beliefs attributable to the fictional author (the f.a.) – a completely reliable source of information about the narrated events – that the reader determines what is true in the story. The reader is supposedly guided here by the text itself, which provides evidence as to the f.a.’s character and psychological idiosyncracies, and by background assumptions – based on knowledge of the real author – as to the historical situatedness of the f.a. But it is open to question whether these resources are adequate to the task (see Davies, 1996).

Semantics of Fictional Discourse

The suggested strategies are supposed to explain how, given an instance of fictional discourse, we can understand what is true in the narrative presented through that discourse. Even if the author does not assert the sentences in such a discourse, it is assumed that the sentences themselves provide us with the content for our acts of make-believe. The use of language in fictional discourse is thus assumed to differ pragmatically rather than semantically from its use in nonfictional discourse (Gale, 1971). This is unproblematic when fictional discourse predicates nonactual properties of actual things – when, for example, Chancery is represented by Dickens as being shrouded in an impenetrable fog. But problems arise when a sentence *S* in fictional discourse contains what appears to be a proper name *N* (e.g. ‘John Jarndyce,’ as it occurs in *Bleak house*), which is not plausibly taken as denoting an actual person, place, or event. Suppose ‘fictional names,’ as Currie terms them, are genuine proper names, and that the same semantic principles apply to fictive and nonfictive

discourse. Then, given the widely accepted ‘direct reference’ theory of proper names (Kripke, 1972), where a proper name contributes to the meaning of a sentence only the individual it denotes, *S* is meaningful only if *N* is a genuinely denoting term. If, by definition, no actual person, place, or event exists that is denoted by a fictional name – if such names are empty – how can we explain our seeming ability to understand sentences containing fictional names, and to hold some of them expressive of what is ‘true in the story’?

Something, it seems, has to give. That is:

- a. fictional names do genuinely denote, or
- b. *S*’s logical form is not as it appears to be, and fictional names do not function as proper names, or
- c. our ability to make sense of *S* is compatible with *S*’s being meaningless.

Option (a) is most famously associated with Meinong (1960), who held that there are nonexistent objects corresponding to unactualised sets of properties. Contemporary Meinongians, such as Parsons (1980) and Zalta (1983), have asserted that fictional characters are nonexistent objects of this kind, and that fictional names denote fictional characters so construed. An alternative strategy is to take fictional names to denote nonactual but possible objects that exist in other possible worlds (Plantinga, 1974; Lewis, 1983). Less ontologically profligate is the contention that fictional characters exist as ‘abstract artifacts’ (Thomasson, 1999) or as theoretical entities required to make sense of our critical practice (Van Inwagen, 1977), where such entities depend for their being on the activities of authors or critics. Those who choose option (a) must explain how fictional names are able to refer to fictional objects, as abstract entities, if names secure their reference through some kind of causal/historical link with their denotata, and how fictional characters are individuated. Arguably, Meinongians are able neither to meet these challenges nor to validate our intuition that authors create the characters in their works (Thomasson, 1999), whereas, so it is claimed, these difficulties can be surmounted if fictional characters are taken to be abstract artifacts.

Option (b) requires that sentences containing fictional names be paraphrased such that they no longer contain such denoting expressions but are meaningful and possess appropriate truth values. Russell (1990), for example, analyzed sentences such as ‘Pegasus flies’ as quantified sentences affirming the existence of something that is a winged horse and flies: fictional names, like all standard names for Russell, are disguised definite descriptions. But this strategy makes sentences containing fictional names come out false

unless by chance there is an existent fitting the relevant description. One response, here, is to take sentences occurring in fictional discourse to have a suppressed 'in the story' operator, while retaining the idea that fictional names, in such contexts, are disguised descriptions (Currie, 1990).

Option (c) grants that fictional names are genuine names and that they are empty, and therefore that sentences containing fictional names are meaningless. We are, however, able to understand fictions and determine what is true in a story, since, in engaging with a fiction, we make believe that the contained sentences are meaningful and that they have the relevant truth values (Walton, 1990).

A problem that is especially acute for those who choose option (b) is accounting for occurrences of fictional names in other kinds of linguistic contexts where it is difficult to deny our commitment to the reality of fictional characters. Discourse **about** fiction includes such utterances as 'N is a fictional character,' 'Tolstoy created N,' and 'N is a better detective than M.' Paraphrases of such sentences offered by proponents of both (b) and (c) seem implausible. However, Meinongians also have to tell a different story about the occurrence of fictional names in such contexts. Zalta (1983), for example, who has held that fictional characters, as nonexistent objects, 'encode' but do not exemplify the properties ascribed to them in the story, maintained that, in discourse about fiction, the characters do exemplify the predicated properties. Van Inwagen (1977) and Thomasson (1999) preserved the surface grammar of such occurrences of fictional names, but at the price of denying that fictional characters literally possess any of the properties predicated of them in the story: for Van Inwagen, such properties are ascribed but not possessed.

Responding to Fictions

Philosophers have also puzzled over the capacity of fictions to elicit fear or other emotions in readers. The puzzle is especially acute given the recent rise to dominance of cognitivist theories of the emotions. According to the latter, my being in an emotional state like fear requires more than that I have a certain feeling or am in a certain affective state. My fearing *x* also requires that I believe that *x* endangers me or someone close to me. Given these requirements, it seems impossible for me to experience genuine fear (or, *mutatis mutandis*, pity) concerning what is narrated in what I take to be a fiction, because I do not believe that anyone is really in danger when I imaginatively engage with such a fiction.

One strategy here is to argue that our affective responses to fictions do have the cognitive foundations

required if they are to be genuine emotions. Perhaps, for example, we believe that real people are endangered or suffering **in the same way** that the fictional characters are represented as doing, and this leads us to feel genuine emotions for these real people. More plausible are analyses that take as central the belief that it is **make-believe**, in the fiction, that I stand in the relation to the fictional characters or situations required if I am to feel genuine emotions for them. According to Walton, such beliefs about the story elicit in us quasi-emotions, which resemble genuine emotions in their physiological and psychological features and which enter into our imaginative engagement with the fiction by encouraging us to **make believe** that we feel the corresponding real emotions (see also Currie, 1990, chapter 5). Neill (1993), however, contended that affective responses elicited in us through our beliefs as to what is fictionally true are often instances of genuine emotions. A third alternative is the so-called 'thought theory,' which holds that such responses (whether or not they are genuine emotions) are engendered not by beliefs about what is the case, actually or fictionally, but by thoughts (Carroll, 1990; Lamarque, 1996) or imaginings (Novitz, 1987) as to what might be the case. (See Hjort and Laver, 1997, for further articles.)

Figurative Language: Semiotics

F Nuessel, University of Louisville, Louisville, KY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term 'figurative language' can be misleading because it has at least two meanings. For many years, texts on literary criticism have used this expression to mean a literary adornment or a stylistic device (Wellek and Warren, 1956: 23, 157). Lakoff and Johnson (1980: 3) noted this conventional usage in their influential work on metaphor. In general, the expression 'figurative language' was restricted to special usage in poetry or rhetorical language. Traditional scholars maintain a strict dichotomy between figurative language and ordinary or literal language. This conventional aesthetic sense of figurative language no longer reflects current usage. Today, the term 'metaphor' has replaced 'figurative language' with the special sense of a cognitive device used to explain how people categorize reality and store abstractions of that physical existence in their brain.

In this article, we will discuss the following issues:

1. Theories of metaphor
2. A selected overview of theoreticians of metaphor and their theories
3. The literal-figurative dichotomy
4. The role of metaphor as a cognitive mechanism
5. The use of metaphor as a knowledge generator.

The literature about metaphor is voluminous, as exemplified selectively in three extensive bibliographies on this topic (Noppen and Hols, 1990; Noppen *et al.*, 1985; Shibbes, 1971). Moreover, important journals devoted to metaphor, such as *Metaphor and Symbol* (formerly, *Metaphor and Symbolic Activity*), *Poetics*, and *Cognitive Linguistics* reflect this burgeoning interest.

The explosion of literature on metaphor reflects some basic shifts in linguistic theory during the 20th

century. In particular, there have been three philosophical revolutions in linguistic theory. In the first part of the 20th century, the North American linguist Leonard Bloomfield (1887–1949) espoused what he called a mentalist approach to the study of language in his book *Introduction to the study of language* (1914). Subsequently, Bloomfield would undergo a philosophical transformation while at Ohio State University under the influence of the behavioral psychologist Albert Weiss (1879–1931). This theoretical conversion appeared in Bloomfield's classic volume *Language* (1933). This behaviorist, or empiricist, view of language received its maximum articulation in B. F. Skinner's (1904–1990) *Verbal behavior* (1957). Its stunning repudiation by Noam Chomsky (b. 1928) in his review in the journal *Language* in the same year represents the beginning of the Cartesian, or rationalist, approach to linguistic theory that continues to be vital today. Neo-empiricism, however, reasserted itself in the influential book *Metaphors we live by* (1980) by George Lakoff (b. 1941) and Mark Johnson (b. 1949).

Traditional discussion of figurative language features a detailed typology of figures of speech. It was a standard practice for those who studied Greek and Latin to receive training in the tropes (derived from Greek for 'manner') of literary language. These include metaphor, simile, personification, and others. This classical view of figurative language as the adornment of a basic literal language influenced literary research and analysis. Wellek and Warren's *Theory of literature* (1956) embodied this approach, and it was highly influential in university literature departments.

Conventional courses in literature often have a component on rhetorical or figurative language. These discussions view such language as stylistic in nature and designed to arouse the reader's interest through these embellishments. The following is a selected enumeration of some conventional tropes

(cf. Danesi and Perron, 1999: 162–164 for a more extensive list).

Theories of Metaphor

Most theories of metaphor can be reduced to two basic ones with some variation. In this section, we will examine these theories and some of their most prominent proponents. First, there is the comparison theory, which may be traced back to the Greek philosopher Aristotle (384–322 B.C.). In this model, metaphor has the form *A is B*, and it suggests an analogy between two items or notions. In this view, a metaphor is a compressed simile. This is the traditional approach, and it includes the resemblance of objects or notions; its usage involves style or economy of statement. A variant of the comparison theory is the substitution theory. The substitution theory means that an inappropriate (figurative) term stands for a proper (literal) one. In this approach, the speaker uses an expression that means, or refers to, something else, thereby requiring the listener to decode the statement. An example is *Martin Luther King is a lion*. *Lion* thus substitutes for the meaning that Martin Luther King is brave and fearless. The essence of the comparison model or the substitution version is based on the premise that there is a basic literal language that is precise and neutral. This language stands in stark contrast to the poetic language generally associated with literature and rhetorical flourishes.

The second major theory is the interactionist theory, which, with its various manifestations and modifications in the 20th century, is the prevailing one today. It contrasts with the comparison view of metaphor. In this approach, there is an interaction of concepts at sentence-level and not word-level, i.e., there is a conceptual association of the elements that constitute a metaphor, and this association gives rise to new meaning as we shall see.

Selected Review of Theories of Metaphor

In this section, we will examine selectively prominent theoreticians of metaphor. These include Aristotle, Giambattista Vico, Groupe μ , I. A. Richards, Max Black, Paul Ricoeur, George Lakoff, and Mark Johnson.

Aristotle (384–322 B.C.)

Aristotle is credited with introducing the word ‘metaphor’ in two of his major treatises (*Rhetoric* and *Poetics* [1997]). The etymology of the word metaphor is from the Greek ‘to carry beyond’ or ‘to transfer.’ This meaning refers to an implied comparison or transference of meaning between two objects formulated as ‘A is B’ or ‘A implies B.’

Aristotle’s view of metaphor is a literalist one, i.e., metaphors stand in contrast to ordinary language. Moreover, his view of metaphor is now known as the comparison theory of metaphor, i.e., ‘A is B’ or ‘A implies B.’ Aristotle’s influential statements about language and rhetoric in *Rhetoric* and *Poetics* continue to be cited after more than two millennia.

The Greek philosopher, and student of Plato (ca. 428–347 B.C.), considered metaphor in *Poetics* (Aristotle, 1997: 150–156). In a general discussion of grammar and etymology, Aristotle provided selected observations on metaphor. In particular, Aristotle stated that “metaphor is the transference of a word of another significance either from genus to species, or from species to genus, or from species to species or by analogy or proportion” (Aristotle, 1997: 150). Aristotle (1997: 151) stated that there are four types of metaphor. His consideration of the first three was terse, while his commentary on the fourth was a bit more expansive.

Aristotle’s first type, that of genus to species, is the expression “my ship stands there” (Aristotle, 1997: 151). In this type of metaphor, which is, in fact, a

Table 1 Some examples of traditional figurative language

Type of figurative language:	Definition:
Conceit	An analogy between two completely distinct notions, e.g., <i>war is peace</i> .
Euphemism	Use of a pleasant word for one that is vulgar or obscene, e.g., <i>powder room for toilet</i> .
Hyperbole	Extreme exaggeration, e.g., <i>he ate half a side of beef</i> .
Irony	Sarcastic wit to mean the opposite of what is meant, e.g., <i>I love that dress!</i> (meaning, <i>I hate that dress!</i>).
Litotes	Understatement to magnify the significance of a statement, e.g., <i>Verdi was not an unimportant composer</i> .
Metonymy	A common feature is used to designate the whole entity, e.g., <i>the pen is mightier than the sword</i> .
Onomatopoeia	The use of words to describe the sounds that they refer to, e.g., <i>the clanging of the bells</i> .
Oxymoron	An observation that is apparently contradictory, e.g., <i>he is a wise fool</i> .
Paradox	An apparently contradictory statement, e.g., <i>dumb as a fox</i> .
Personification	The representation of a concept or an object as living entities, e.g., <i>Death came through the door</i> .
Rhetorical question	A question that is not intended to be answered, e.g., <i>do you understand me?</i>
Simile	An overt comparison with words such as <i>like</i> or <i>as</i> , e.g., <i>he floats like a butterfly</i> .
Synecdoche	The part stands for the whole, e.g., <i>the law (= the police) broke down the door</i> .

synecdoche, 'stand' is the genus and 'lying at anchor' is the species.

The second type (species to genus) offered by Aristotle (1997: 151) is "verily ten thousand noble deeds hath Odysseus wrought," in which case 'ten thousand' signifies 'many.' Again, this is a synecdoche, and some critics have labeled it 'clumsy' because the choice of 'ten thousand' to mean 'many,' even though it may have been a commonly accepted expression in Aristotle's time, is definitely not novel.

The third metaphor type, and the exemplar for species to species is "with the blade of bronze drawing out the life" (1997: 151) and "cutting with the unwearied bronze" (1997: 151). In these cases, 'drawing out' means 'cutting,' while 'cutting' means 'removing something.' Both mean to 'take away.' Umberto Eco (b. 1932) argued that this third type of metaphor was the quintessential one on which subsequent theories base their own views of the nature of metaphor (1984: 92). Aristotle's third type of metaphoric exemplar perhaps best illustrates 20th-century views of metaphor as a tripartite concept, e.g., I. A. Richards's (about whom more will be said below) notion of a metaphor as consisting of a tenor (the metaphORIZED term), a vehicle (the metaphORIZING term), and a ground (the meaning created by the interaction of the tenor and the vehicle). This type of metaphor has the form (A (B) C), i.e., A is the tenor, C is the vehicle and B is the ground or the intermediary term which provides the meaning of the metaphor supplied by the interpretant, or the person who seeks to make meaning of the comparison. The tenor (often called the topic now) is the A-referent (what is talked about in the metaphor). The vehicle is the C-referent (something concrete or familiar) and the ground is the meaning of the comparison, or the B-referent. In the sentence, *Mary is a witch*, 'witch' is the vehicle, 'Mary' is the tenor or topic, and the meaning created by the connection of these two terms is the ground. Cultural context will assign a specific meaning to the vehicle of a metaphor.

The fourth and last type of metaphor, with Aristotle's overt statement that it is by analogy or proportion, involves a formula with four elements. Aristotle offered two examples. The first is the analogy of the "shield of Dionysus" and the "cup of Ares" (Aristotle, 1997: 151). In this four-part proportional metaphor, the four terms may be delineated in the following way as a subject/instrument relationship: Dionysus : cup :: Ares : shield. This is to say that 'shield of Dionysus' is a metaphor for 'cup,' and 'cup of Ares' is a metaphor for 'shield.' Thus, the cup is to Dionysus as the shield is to Ares. Eco (1984: 95) pointed out that there are similarities and differences in this metaphor. Dionysus and Ares are both gods (the former of joy and

peaceful rites, the latter of war and death). The cup and shield are alike due to their roundness. The hearer must pick out the similarities and discard the differences. If there are too many differences, the metaphor is unsuccessful.

In Aristotle's second example (Aristotle, 1997: 151), "old age [is]... the sunset of life," attributed to Empedocles (5th century, B.C.), there is a proportion or analogy that consists of four terms, namely, A : B :: C : D, i.e., old age : life :: sunset : day. This proportion is different from the above metaphor because it involves the proportion A : B :: C : D. In this metaphor, the proportion may be stated in the following way: A = old age, B = life, C = evening, D = day. In this sense, A is to B as C is to D. Hence this proportional analogy is a comparison of the life cycle to the diurnal cycle.

Thus, in a succinct narration, Aristotle provided us with our initial knowledge of the metaphor, and one to which all future scholars would refer over the millennia. Aristotle's views on metaphor contain three basic notions: (1) there is an exchange of properties between two entities to increase understanding; (2) there is a cognitive dimension to metaphor, albeit suggested rather than overtly stated, and Aristotle does not explain this; and (3) the pair metaphor/metonymy represents the essence of semiosis and human thought.

It is also clear that Aristotle left a legacy that includes a doctrine of signs, when he observed that words are tripartite objects which consist of a form (pronunciation), a referent (what the word alludes to), and a meaning. In one of his statements on metaphor, Aristotle (1997: 153) stated that "... making good metaphors requires the ability to grasp resemblances." In effect, this observation is a comparison model of metaphor. Aristotle's comparison theory has met with criticism over the centuries, though its basic premise remains intact.

It should be noted that the Roman rhetorician Quintilian (ca. 35–100 A.D.) espoused Aristotle's comparison view of metaphor and claimed that it was a substitutive process. This substitution theory argued that in the metaphor 'John is a rat,' the use of 'rat' for 'man' (in the sense of a vile and loathsome creature) was simply a deviation from a pristine literal language. Neither Aristotle nor Quintilian offered a psychological explanation for the pervasive use of metaphor in world languages. That would not take place in any systematic way until the 20th century.

Giambattista Vico (1668–1744)

The Neapolitan empiricist philosopher had many interesting things to say about metaphor, and his observations presage important work in the 20th century,

and it is for this reason that we discuss his work here. In his treatise *The new science* (1968), Vico spoke about figurative language, in particular, metaphor. Reawakened interest in Vico in the 20th century corresponds to a renewed interest in metaphor research and the way in which Vico conceptualized it. Vico differs from his rationalist counterpart, the French philosopher René Descartes (1596–1660), whose views on language are quite distinct. Descartes was a rationalist who believed that people possess an innate linguistic faculty rather than an acquired one.

Vico's views on language consist of a series of basic epistemological principles that propose how we acquire knowledge about the world and how language develops. His stance on language in general, and metaphor in particular, may be stated as axioms about the origination of language and thought. We will now discuss this set of stages or steps in the development of thought and language, and, ultimately, metaphor.

First, thought is corporeal. We acquire our knowledge of the external world through our senses. In this regard, Vico espouses his empiricist view of epistemology by arguing that our knowledge has a sensory basis, i.e., we learn about the world by experiencing it first and foremost through vision, as well hearing, touch, smell, and taste. We then use this information to categorize this knowledge in a systematic way through our contact with the external world. Second, thought is representational. This means that it is imaginative or image-creating. These visual, culturally-determined patterns allow us to access information retained in our memory iconically. The linguist Ann Viberg noted that in the languages of the world, most of the predicates that are synonymous with the verbs of knowing and understanding relate to visual intake. In fact, prior to the development of a systematic language system with a phonology, morphology, syntax, semantics, and lexicon, it is likely that prelinguistic peoples utilized visual signals and signs including primitive pictures for communication as evidenced by the drawings and paintings at various archaeological sites worldwide, e.g., the cave paintings of Altamira, Spain. Third, thought has gestalt (German for configuration)-like properties, i.e., it consists of segments or parts that have a greater significance than its individual constituents. This axiom means that we configure thought through a series of components that build from the concrete to the abstract. Fourth, thought has an ecological basis. For Vico, human language evolved through a series of stages that included gestures that stood for a single article (tool) or concept (fire), and these symbolic gestures developed over time into complex verbal systems. Finally, thought and its verbal manifestation speech is, in fact, metaphorical in nature. For Vico, the process

by which thought and language developed means that language is metaphorical, because we express ourselves through categories based on real-world experience, which we internalize in our brain in meaningful components.

The essence of Vico's cognitive scientific views of metaphor appears in the following citation "...in all languages the greater part of the expressions relating to inanimate things are formed by metaphor from the human body and its parts and from the human senses and passions. Thus, the head for top or beginning; the brow and shoulders of a hill..." (Vico, 1968: 129). This association of external reality with the bodily experiences of that reality is the essence of the new empiricist linguistics which was encapsulated in Lakoff and Johnson's (1980: 59) observation that "...we typically conceptualize the nonphysical *in terms of* the physical..." i.e., the unknown in terms of the known.

I. A. Richards (1893–1979)

Richards introduced some basic notions on the structure of metaphor in his classic treatise *The philosophy of rhetoric* (1936). In the fifth and sixth lectures ('Metaphor' and 'The command of metaphor') of the Mary Flexner Lectures series at Bryn Mawr University, he discussed metaphor in revolutionary terms. In his fifth lecture, Richards (1936: 90) noted that metaphor has traditionally meant "...a grace or ornament or *added* power of language, not its constitutive form." In this groundbreaking paper, Richards would go on to espouse his interactionist theory of metaphor. He argued, in fact, that metaphor is ubiquitous in language, and, by implication there is no literal-figurative speech dichotomy. Richards then introduced new expressions for the three parts of a metaphor, namely, 'tenor,' 'vehicle,' and 'ground.' In a prototypical metaphor, the tenor is the topic or the unknown part in Richard's triadic configuration. The vehicle is the part that comments on the topic, and the ground is the actual meaning created by the interaction of the tenor and the vehicle.

In this theoretical model, Richards builds upon Aristotle's claim that metaphor is the comparison of two apparently dissimilar items (*A is B*) or the substitution of one item for another (*A stands for B*). In Richards' model, however, there is an interaction, i.e., parts of the two entities remain separate and distinct but there is a domain of shared properties in which a new meaning is created. This area of shared properties may be configured as (*A(X) B*). In this model, A is the tenor (topic) or the unknown aspect of the metaphor. B is the vehicle that is a familiar object or concept. X in the equation just given is the ground or meaning produced by the association of the tenor (A)

and the vehicle (B). Thus, the previously mentioned statement *John is a rat* causes the hearer to think or experience one thing in terms of another. In this case, we are invited to draw comparisons between the behavior and traits of a person (*John*) and those of an animal (*rat*). Clearly, a human and a rat are distinct, yet they may share certain traits, e.g., animate, furtive, sneaky, filthy, to name but a few domains of similarity. It is in these areas that new meanings are created. In this specific case, the prototype metaphor or conceptual metaphor (see Lakoff and Johnson below) is PEOPLE ARE ANIMALS (conceptual metaphors are presented in upper case letters by convention and we will follow this format throughout). The specific case here causes the hearer or reader to draw inferences about the shared properties of *John* and a *rat*. To be sure, the similarities in this instance are not pleasant ones. We can thus state that *John* is the tenor or topic, *rat* is the vehicle, and the ground is the meaning of this metaphor, i.e., the conceptualization of John as a vile person. The juxtaposition of the A component (tenor/topic) and the B component (vehicle) is thus responsible for an interaction that provides a new meaning that had not previously existed. Although Richards uses the term ‘interaction’ in his writing on metaphor, this expression would be most closely associated with Max Black (see below) who gave it currency.

As we shall demonstrate, scientific discovery relies heavily on the use of metaphor to create new knowledge about the world by this interactionist strategy. Many scientific breakthroughs have occurred by using this epistemological strategy, e.g., William Harvey’s (1578–1657) use of the machine metaphor to describe the physiological phenomenon of the movement of the valves of the heart.

Richards (1936: 92, 93) also points out that metaphor is “omnipresent” in speech. He notes that even in scientific and technical language, metaphors are ubiquitous. Although Richards did not carry out an empirical analysis of this assertion, Pollio and his associates (1977) did just this, and they discovered that novel and dead metaphoric language permeated speech. Richards thus takes the position that there is no literal-figurative dichotomy, i.e., the claim that there is a basic ‘ordinary’ language that is embellished by the use of colorful figurative language.

In yet another way, Richards is a precursor of the theoretical metaphorology espoused by George Lakoff and his advocates. He states that thought is metaphoric. By this, he means that metaphor constitutes the essence of epistemology. We acquire knowledge about our world and ourselves by converting concrete experience into abstract manipulable units of that experience that allow us to categorize it and refer to it.

Max Black (1909–1988)

Max Black provides another perspective of the interactionist view of metaphor. In his illuminating discussion on the form of metaphor (Black, 1981 [1955]: 77–78), Black enumerated seven basic points about the interaction model of metaphor. First, a metaphor consists of two topics, a primary and a secondary one. Next, these topics are not monolithic entities, but rather they are complex, well-organized groupings of properties. Third, the metaphor affixes to the primary topic a complex of analogous insinuations attributable to the secondary topic. Fourth, in general, these inferences involve commonalities, though, occasionally, there are startling associations. Fifth, metaphors are selective in their implications, i.e., they choose only certain aspects of the secondary topic that apply to the primary one. Sixth, transformations in the lexical meaning belonging to the same family may be metaphoric transfers. Finally, no simple rule for shifts in meaning exists, nor is there a good explanation for why some metaphors are accepted and others are not.

Schroots (1991: 222) best captured the essence of Black’s interactionist view of metaphor in the following observations:

1. Metaphors are concerned with systems of ideas;
2. Such systems are specially constructed;
3. Metaphors are projective in that they allow one field of thought (subject) to organize another, whether by selection, filtering, focusing, or other means; and
4. Models are extended and systematic metaphors.

The celebrated semiotician Charles Peirce (1839–1914) espoused the concept of ‘abduction.’ Simply stated, this is an educated guess. With regard to metaphor, abduction allows the hearer to make a meaningful association between the tenor (now generally called the topic) and the vehicle, i.e., the A and the B components of a metaphor. Abduction would thus allow the hearer to engage in meaningful hypotheses about what the associations between the tenor and the vehicle might be. As noted above, if the associations are tenuous or oblique, then the metaphor will be unsuccessful.

Groupe μ

Groupe μ consists of a cadre of scholars at the University of Liège in Brussels who published *A general rhetoric* (1981) that dealt with figurative language. It predated Lakoff and Johnson’s groundbreaking work on metaphor but offered an excellent overview of a structuralist approach to metaphor research. This group represents the ideology of Ferdinand de

Saussure (1857–1913), Louis Hjelmslev (1899–1965), Emile Benveniste (1902–1976), Algirdas Julien Greimas (1917–1992), Roman Jakobson (1896–1982), and others of the Structuralist school (see more about this linguistic school below).

Paul Ricoeur (1913–2005)

Paul Ricoeur's study (1977) of metaphor is considered to be one of the major statement on metaphor. In this important volume, Ricoeur authored eight essays on metaphor. Ricoeur appropriately began with a consideration of Aristotle's views as the prime mover in metaphor research for more than two millennia. Next, he reviewed the French writer Pierre Fontanier, whose taxonomic approach was inadequate to explain metaphor. In his third study, the author examined metaphor as a sentence-level or a word-level device. In his fourth and fifth studies, Ricoeur investigated structuralist views of metaphor. The sixth study moved to the discourse-level of metaphoric analysis. The seventh paper discussed reference, and the final one dealt with the philosophical underpinnings of metaphor research. What makes this volume valuable is the author's ability to analyze the multiple approaches to metaphor in an objective fashion. Ricoeur brought to our attention that the study of metaphor means coming to grips with the essential nature of language – meaning and semantic deviation.

George Lakoff (b. 1941) and Mark Johnson (b. 1949)

Lakoff and Johnson articulated an elaborate theory of metaphor as a cognitive construct. Their collaborative and individual work has done much to advance metaphor research in the past quarter century. In this section, we shall devote an extended discussion to their contributions to metaphorology.

In *Metaphors we live by* (1980), Lakoff and Johnson discussed the notion of the conceptual metaphor. Their approach to the study of metaphor is now known as Conceptual Metaphor Theory. Thus metaphors such as the previously stated example *John is a rat* (discussed previously) is part of the general conceptual metaphor which equates qualities of people with qualities of animals. Sometimes, these are positive (*Mary is a bunny rabbit*), and in other instances they are negative (*John is a warthog*). The preceding three examples belong to the conceptual metaphor PEOPLE ARE ANIMALS.

Conceptual Metaphor The conceptual metaphor PEOPLE ARE ANIMALS is relatively common. In recent times, the generic term predator, those animals that live by preying on other, weaker animals for

sustenance, has come into frequent use. Predatory animals include, but are not limited to, lions, tigers, and pumas. When people are labeled as predators, this is a subcategory of the PEOPLE ARE ANIMALS conceptual metaphor. This type of metaphor is common in the media, especially when referring to certain types of heinous crimes. This metaphor involves those people who prey upon people who are weaker, e.g., children, older adults, or people with disabilities. The following sentences illustrate this usage.

1. The man *stalked* his victim for days.
2. The outlaws *hunted* their prey surreptitiously.
3. The criminal *pursued* his quarry relentlessly.

The sense of this subcategory of PEOPLE ARE ANIMALS is decidedly negative, because it evokes powerful negative emotions due to its unpleasant associations. Conceptual metaphors thus consist of two parts that are called domains. The first is a source domain (vehicle, or the known, sometimes labeled the B-referent) and a target domain (tenor or topic, or the abstract element, sometimes called the A-referent). In the PEOPLE ARE PREDATORS conceptual metaphor, *people* is the target domain, or the topic itself, while *predator* is the source domain, or the vehicle that delivers the metaphor to the hearer. A metaphor is thus the mapping of one domain into another.

In the Lakoff and Johnson model, metaphor is not a mere deviation from an underlying literal language that functions as a linguistic ornament. Rather, metaphor is now viewed as a cognitive process that allows the mapping of a source to a target domain to enhance comprehension of the unknown in terms of the known. Thus, for Lakoff and Johnson (1980: 5, emphasis in original) “the essence of metaphor is understanding and experiencing one kind of thing in terms of another.”

Other examples of conceptual metaphors include the ARGUMENT IS WAR metaphor, exemplified by such common examples as the following sentences.

ARGUMENT IS WAR

1. They *fought* my claims constantly.
2. I *won* that point.
3. They *beat* us in court.

An additional illustration of conceptual metaphors follows. It should be noted that many of these are rooted in the proverbial language of a culture. In English, ‘time is money’ is simultaneously a proverb and a conceptual metaphor.

TIME IS MONEY

1. We will *buy back* your time with release time.
2. *Budget* your time for each section of the test.

3. *Donate* some of your free time to this cause.

The number of conceptual metaphors in a language is potentially unlimited. Different cultures, however, will focus on and highlight different aspects of these metaphors.

Metonymy A subcategory of metaphor is metonymy. Metonymy refers to the use of one element to refer to another that is closely related. The following examples illustrate this cognitive mechanism.

1. He loves *Cervantes*. (Cervantes = the writings of Cervantes)
2. She's in *opera*. (opera = the profession of operatic performance)
3. *New hair* made John very happy. (new hair = surgical procedure to implant hair).

Synecdoche Synecdoche is a subtype of metonym. It is the conceptual process by which the part stands for the whole, i.e., a segment of an object stands for the entire object. The following examples depict this cognitive device.

1. The *SUV* is destroying the environment. (= the overuse of the this type of vehicle is destroying our limited natural resources)
2. A few good *arms* will help us win this baseball game. (= good pitchers will help the team to win the baseball game)
3. The *brains* in that university are world-class. (= the intelligent people on the faculty).

Marcel Danesi (1946–) and Paul Perron (1940–) introduced the expression ‘conceptual metonymy’ as a parallel to conceptual metaphor as a way to organize reality in different cultures (1999: 176). Conceptual metonyms are another meaning-making tool at our disposal. Among the categories they suggest are the following ones.

PRODUCER FOR THE PRODUCT

1. Give me a *Perrier*®.
2. I just bought a *Ferrari*®.
3. I own a *Miró*.

THE PLACE FOR THE INSTITUTION

1. The *White House* just denied complicity.
2. *Fleet Street* is predicting a recession.
3. *Vatican City* issued a papal decree.

During the decade of the 1980s, Lakoff and Johnson presented a persuasive model of metaphor to explain how we convert concrete experience into abstract concepts and store the information gleaned from

those experiences in our brains. In the next section, we shall discuss how Lakoff and Johnson described this process.

The Image-Schema The image schema is a key element in the theoretical construct of Lakoff and Johnson's conceptual metaphor. Johnson (1987: 29) pointed out that an image schema “...operates at a level of mental organization that falls between abstract and propositional structures ... and particular concrete images. ...” Johnson argued that in order for us to provide structure to our experience and to be able to recall it, there has to be a pattern and order in our perceptions, actions, and conceptualizations. This arrangement occurs through image schemas that consist of shapes, patterns, and images that provide regularity to our experience. Schemas allow us to categorize and catalogue our experienced reality by associating the unknown with the known and allowing us to decide where the new information belongs. The experimental psychologist, Eleanor Rosch (1973), showed that people do this on a regular basis. In this way, conceptual metaphor, and its related forms conceptual metonymy and conceptual synecdoche, represent this cognitive process.

Johnson pointed out that the image schema is not a photographic reproduction of experienced reality; rather, it is a mental icon that is malleable in its format, i.e., is not a fixed form. It allows us to fit new experiences into a somewhat amorphous pattern or shape and give it meaning. Image schemas may represent any of the five senses (sight, hearing, touch, taste, smell). Selected linguistic analogues include the following expressions:

1. A sight to behold (sight)
2. The roar of the crowd (sound)
3. A clammy feeling (touch)
4. A sweet flavor (taste)
5. The smell of greasepaint (smell).

Because image schemas are such an ingrained part of language, we often do not recognize them.

Lakoff's (1987: 122–124, 138–142) work on fuzzy grammar pointed out systematic grammatical reflexes of what would come to be called image schemas. Lakoff showed that English utilizes certain phrases and expressions to express membership in prototypical categories. Thus, there are certain objects that clearly belong to a specific category, e.g., birds (winged, feathers, ability to fly) such as cardinals and bluejays. Other animals either do or do not belong to this category or belong only marginally. In these cases, expressions such as *a kind of*, *sort of*, *essentially*, and many more are employed to

situate these objects at the periphery of this category. Thus, the sentence *a penguin is a kind of a bird* indicates our placement of this animal at the border of this image-schematic classification. Ronald Langacker would develop this notion to a far greater extent in his ‘cognitive grammar’ model of linguistic theory (see below).

Lakoff and Johnson’s innovative research thus represents a continuum in the analysis of metaphor dating back to Aristotle. They utilize pre-existing scholarship as the basis for their conceptual metaphor theory. At the beginning of the 20th century, researchers such as Karl Bühler (1879–1963) initiated experimental research in the paraphrasing of metaphor-rich proverbial language. By the middle of the 20th century, psychologists including Charles Osgood (1916–1991), B. F. Skinner (1904–1990) and Solomon Asch (1907–1996) began to examine metaphor. It was I. A. Richards and Max Black, however, who most influenced Lakoff and Johnson’s research with their interactionist view of metaphor.

Ronald W. Langacker (b. 1942)

The theoretical linguist, Ronald W. Langacker, articulates Lakoff and Johnson’s views on conceptual metaphor in his cognitive grammar. Langacker notes that the Lakoff and Johnson view of metaphor is one in which metaphor is basic to epistemology. As stated previously, metaphor involves mapping a source domain (vehicle = the known) and a target domain (topic or tenor = the unknown). In this approach, the projection of a source field onto a target field is a metaphoric process. In this sense, as Danesi and Perron (1999: 175) noted that metaphor is “...the ability of the human brain to convert experience into abstraction via the mapping of some source domain onto a target domain to produce an abstract concept.” In his extensive research, Langacker provides specific examples from various languages to illustrate how his version of cognitive grammar works. What Langacker does is connect the conceptual metaphors to grammar. Specifically, he relates grammatical categorization and concept formation. The following example illustrates Langacker’s line of argumentation.

Lakoff demonstrates that certain aspects of English grammar reflect the image schema, the essential basis for Lakoff and Johnson’s notion of the conceptual metaphor. Langacker (2002: 1–32) showed a relationship between grammar and concept formation. In cognitive grammar, a metaphorical theory of grammar, we receive input from the external world. This input is processed at the experiential level, i.e., through our senses. Next, this information is

converted into image schemas such as shapes and so forth. Third, the image schemas are transformed into conceptual metaphors/metonyms/synecdoches. Finally, this totality of information is transformed into the linguistic categories of grammaticalized or lexicalized forms.

A succinct, albeit simplified restatement of one example, of the many presented by Langacker (2002: 149–163) suffices here. The verb *go* exemplifies the grammaticization, or the projection of certain basic concepts into the grammar of a language. The verb *go* has the meaning of motion and, subsequently, it evolves into a future meaning. This occurs because the original meaning of ‘movement from the speaker,’ a spatial concept, is transferred to a temporal domain. On the one hand, this verb means to move from point A to point B, e.g., $A \rightarrow B$. On the other hand, it signals a more abstract movement through time, i.e., an activity that will be carried out at a future time. In this sense, English and many other languages of the world combine spatial and temporal movement into a single verb. To be sure, this explanation is a bare-bones discussion of the complexities involved this semantic shift from space to time, but it serves to show that conceptual frameworks may be grammaticized or shifted from experience to an abstract grammatical notion of movement.

Literal Versus Figurative Language

The assertion that figurative language derives from a basic literal language has been a matter of discussion for some time. This underlying assumption thus separates language into two distinct categories – one primary, the other secondary. For nearly 25 centuries, since Aristotle’s commentary, the assumption of the literal-figurative language dichotomy has gone virtually unchallenged, albeit certain philosophers such as Vico have indeed insinuated that all language is metaphorical. As noted above, Aristotle’s significant statements about metaphor held sway, with certain precursory and insinuating statements to the contrary, until the 20th century.

The essence of the literal-figurative debate revolves around whether or not metaphor is a deviation from some pristine ordinary language or whether it is a basic form of linguistic expression. The essential question relates to whether or not metaphor is derivative or basic. To respond to this question, it is necessary to consider briefly some hypotheses about the origin of language. In this regard, Danesi (1993: 1–29) discussed in some detail the likely, lengthy progression of the process of linguistic evolution. Danesi’s response was Vichian in that he subscribed to Vico’s empiricist view that language originates

through gestures that signified basic concepts. Subsequently, these isolated gesticulations and primitive interjections became codified into an ever-increasing abstract set of oral symbols that we call language. This process involves an abstraction or a metaphorization of these primitive experiences that evolved from gesture to symbolic utterance to a fully developed linguistic syntax. Many of these primal metaphors become unrecognizable and they now appear to be literal linguistic expressions. Because these basic metaphors have become so commonplace and are now unrecognizable, we assume that they are literal.

In the literalist camp, Mac Cormac (1985: 73) defined literal language as “the use of language to express concrete objects and events. When we employ ordinary words in their ordinary dictionary senses to describe events or situations that are publicly perceptible, we are speaking literally.” Even though Mac Cormac is an ardent literalist who believes that there is a distinction between these two forms of language, he conceded that as a literal language apologist, he (Mac Cormac, 1985: 78) must admit that his explication of literal language presupposed an elementary metaphor, namely, that the world consists of natural categories.

In his 1936 discussion of metaphor, Richards was among the first to break with tradition and state that metaphor is essentially omnipresent in language. By making this bold statement, he revolutionized prevailing wisdom about metaphor. It is no longer deviation from standard or literal language, it is, in fact, the essence of language. Richards noted that the boundary between literal and figurative language was not fixed or constant.

Empirical research carried out by Pollio *et al.* (1977), for example, provided persuasive evidence for what Richards called the omnipresent nature of metaphor in ordinary language. Specifically, their research showed that individual speakers uttered approximately 3000 new metaphors per week, as well as 7000 idioms that are frozen metaphors.

Lakoff disputed the literal-figurative dichotomy. In an important article on this aspect of language, Lakoff (1986: 292) pointed out various distinct meanings of literal language. It is possible to state Lakoff's views of the misconceptions of the word ‘literal’ in this debate in at least four different ways. First, literal language diverges from special uses of language such as literary language. Second, there is a language for a particular subject matter. Third, there is a language that has no secondary meaning. Finally, there is a logical language that may be true or false. Lakoff points out that these four basic assumptions of a literal-figurative dichotomy are not tenable. In fact, the four meanings of ‘literal’ converge.

Semiosis and the Signifying Order

The signifying order is the means by which a society or a culture codifies meaning. It is a tripartite process, as Danesi and Perron (1999: 70) pointed out. It consists of semiosis (the capacity to comprehend and create signs), representation (the process of using signs to refer to objects and concepts), and the signifying order (the cultural complex employed by a given culture to impose representation and order in that society).

Sebeok (1920–2001) developed a modeling system to describe this process of the comprehension and production of signs (Sebeok, 1994: 116–127). The primary modeling system is the mental system that receives input from the external world. This system is the one that underpins the representational operations of replication, simulation, imitation, and indication. Next, the secondary modeling system is that mental system that produces projections of primary or concrete models into abstractions. In this sense, language exemplifies this modeling system because it utilizes primary signs to create linguistic signs. The tertiary modeling system extends primary and secondary modeling systems into an elaborate schema of cultural signs (literature, the performing and representational arts) to its most abstract and significant levels. The combination of these three systems, and most especially the tertiary modeling system is metaphorical, in nature because the cultural signs stand for different aspects of the culture, e.g., an Italian opera is a higher order system of signs (verbal, musical, artistic) that incorporates many essential aspects of the Italian culture.

Metaphor production is a special example of this process that involves, as Danesi and Perron (1999: 69) discussed, a series of stages that includes environmental input into the bodily senses through a process of semiosis. This input is then represented in the mind and ultimately displayed in the culture through the signifying order. In language and in art, this signifying order manifests itself through metaphoric concepts. The actual activity of sign-making is re-presentation, i.e., the presentation knowledge and information again in some new symbolic format, e.g., writing, painting, sculpture, architecture, and so forth. There is an ordered process for semiosis, namely, external input (through the senses) → re-presentation (the use of signs to refer to these external stimuli) → culture (the culture in which person lives gives meaning to the signs of that culture). One of the roles of educating a child is to teach it the salient signs of a culture. Parents engage in this activity with their children from infancy on. The signs of a specific culture are both verbal (language) and nonverbal (kinesics,

paralanguage, proxemics). Cultural signs are transmitted from one generation to another via literature, and the plastic and representational arts. Oral societies use memorized and recollected narratives, a kind of auditory cultural history to transmit their cultural signs from one generation to another. These codified signs must be learned by members of other cultures. In the deaf community often via various forms of translation, these signs take the form of meaningful systematic visual gestures.

The essence of semiotics, as Sebeok (1994: 11) pointed out, is the relationship expressed in the medieval Latin expression *aliquid stat pro quo*, i.e., 'something stands for something else.'

Charles Sanders Peirce would expand this bipartite definition (object-sign) of the sign to a tripartite one, in which interpretation becomes the third element (object-sign-interpretant). In essence, a sign is generally considered to consist of three components: (1) the sign or representation (something employed to stand for something else); (2) the object or referent (what is referred to by the sign); and (3) the interpretant (a person's understanding of the sign-object relationship, determined by culture). Medical analysis, one of the oldest recorded professional practices, provides a good example of this triadic system of meaning. In classical medicine, the four signs of illness were *fervor* 'fever,' *dolor* 'pain,' *rubor* 'redness,' and *tumor* 'swelling.' These signs or symptoms, alone or in combination, stand for various physical maladies to be interpreted by the physician. Over the years, symptomatology has become quite sophisticated, in part, aided by new knowledge and sophisticated technology. A good example of the medical sign is the aggregation of symptoms that stand for a stroke, namely, sudden numbness or weakness of the face or limbs, especially on one side, confusion, vision problems, and so forth. All of the medical signs converge to form a systematic pattern of a particular medical problem. The correct interpretation of this cluster of meaningful signs results in a diagnosis. The grouping of physical signs stands for specific illness or syndromes as interpreted by a trained physician.

The Uses of Metaphor

Metaphors may generate new knowledge. As noted above, this is often the case in science. The ability to explain the unknown in terms of the known, the abstract in terms of the concrete, make them ideal vehicles to expand knowledge and to enhance comprehension.

In any discussion of metaphor as a knowledge creator, especially in science, it is necessary to discuss three basic notions: (1) analogy, (2) model, and

(3) metaphor. It is not uncommon to find these terms used interchangeably, though, in fact, they are distinct. Analogy, a term used by Aristotle in the definition of his fourth type of metaphor, has at least two meanings. First, it may mean similarities in two objects that are otherwise distinct. Secondly, it is a kind of inference by which it may be deduced that objects that bear some similarity may also be comparable in other ways. A model in the scientific sense does not refer to a scale model, but rather to an analogy. A metaphor in science is again a comparison of the unknown in terms of the known. Thus, a miniature planetary system stands for the Bohr-Rutherford atom, a container of billiard balls in motion for the kinetic movement of gases, the computer for the brain, and so forth.

A model may be an object, often of reduced scale, that stands for the actual object. In architecture, scale models of buildings are commonplace. A second meaning is a tentative theoretical construct intended to function as a testing device. In her discussion of 'model,' Mary Hesse (b. 1924) uses the example of the dynamic model of gases, in which gases are seen as an assortment of billiard balls in random motion. In this model, motion and impact are the shared features, while color, hardness and shininess are irrelevant (Hesse, 1966: 7–11). The shared elements are a positive analogy; those that are not significant constitute a negative analogy. Other factors that play no role in the analogy are neutral. In this view of a 'model,' the primary model (model₁) alludes to the imperfect copy (billiard balls) minus the negative analogy. The second use of the term 'model' (model₂) is the second copy with its positive, negative, and neutral analogies.

A few examples of a model are in order. The Bohr-Rutherford conceptualization of the atom is explained in terms of the planetary system, i.e., the different parts of the atom with its component electrons and protons which function much as the planets that revolve around a central solar system. In this case, the planetary system is model₁ and the Bohr-Rutherford atom is model₂. Additional examples of this use of modeling include comparisons of the human or animal body to a machine, or the brain to a computer.

We shall now discuss a number of specific examples of how science and education use metaphors and models as a way to advance knowledge. It must be noted that a model is an actual object (planetary system, billiard balls, computers) already known to the audience. The theory used to explicate the scientific innovation uses the model metaphorically, once again, to describe the unknown in terms of the known.

Theory-Constitutive Metaphors

Scientists use metaphors to explicate their theories in a way that will make them comprehensible to their intended audience. This public, however, is often limited to fellow scientists. Successful metaphors, i.e., those that introduce a novel perspective in a branch of science, tend to capture the imagination of an entire generation of scholars who embrace its basic meaning and apply its newly created insights to previously unresolved problems. This notion of theory-constitutive metaphor merits review at this juncture.

Thomas S. Kuhn's (1922–1996) book *The structure of scientific revolutions* (1970) argued that there are periods of normal science when scientists work within a single paradigm or model commonly accepted by the practitioners of a particular science until there is what many call a 'breakthrough.' In his discussion of paradigm, Percival (1976: 286–287) noted that scientific paradigms consist of symbolic generalizations, such as Einstein's $e = mc^2$, which are elegant, yet simple explanations for previously unexplained phenomena. Paradigms also consist of models or conceptual analogies that offer members of a given scientific community an ontological framework. Members of these groups share theoretical values to evaluate competing theories within their framework. Finally, they use exemplars to show how their theory resolves complex problems that earlier theories could not. Periodically, this normal science is rejected, most often by a single scientific genius who provides answers to residual problems in the prior theory as well as making significant new strides in the field of inquiry. What we shall see is that scientific revolutions are often founded on novel metaphors that reject those of the theory they have supplanted.

Linguistics 20th-century linguistic theory provides an excellent example of the use of metaphor to change theory. During the last century, two major theoretical paradigms in linguistics emerged. The first was exemplified by Leonard Bloomfield's *Language* (1933), with its empiricist view of language. In this book, linguistic knowledge derives from external sensorial experience. In *Verbal behavior* (1957), B. F. Skinner, the U.S. psychologist, elaborated these empiricist views on language through his stimulus-response approach, one that greatly influenced second-language education in the 1960s. A second theoretical approach to linguistic analysis emerged with Noam Chomsky's *Syntactic structures* (1957) and *Aspects of theory of syntax* (1965), and its clearest exposition in Chomsky's *Cartesian linguistics* (1966), with its rationalistic approach to language

acquisition, i.e., humans are born with an inherent language acquisition device.

Both of these linguistic theories employ distinct metaphors. In brief, the Bloomfield model, or American Structural Linguistics, language may be viewed as a stack of boxes that represent levels of analysis (phonology, morphology, syntax). The linguist begins with the lowest box, or level, and then, presumably utilizes a series of analytical tools (item and arrangement analysis, item and substitution analysis) until the highest level (syntax) is attained. It utilizes a down-up metaphor. This approach utilizes the empiricist notion that language is accessible and analyzable through the senses. Structuralism likewise introduces language as a physical, biological, organic entity. Hence, phonemes function as atoms, syllables as molecules, and words as cells, though it was rare that structural analysis went beyond these linguistic units to higher order linguistic units such as sentences and discourse. Again, analysis starts with the phoneme, or basic unit of sound in a language, since its metaphoric model were those sciences which progressed from the smallest unit to the largest one. The conceptual metaphors that guided structural linguistic analysis, as we shall see, are very different from that those organized transformational-generative linguistic theory.

One of the problems with the structuralist model, and one that the next generation of linguists would address in a comprehensive fashion, is its failure to provide an analysis of syntax. In the succeeding generation, the transformational-generative model of language, Noam Chomsky viewed language as an abstract system genetically embedded in the brain. In this model, syntax is central, while phonology and morphology are lower-level, somewhat superficial manifestations of the abstract syntactic level. In this theoretical model, the brain functions as a computer, and it generates an infinite number of grammatical sentences via a limited set of simple rules. This model employs a left-right metaphor for analysis (rewrite rules). Transformational grammar also uses the metaphor of a tree structure with terminology such as branching, pruning, chopping, and nesting to describe its processes. Finally, geometrical and mathematical metaphors predominate, e.g., mapping, transforming, and propositional calculus. It is this use of mathematical metaphors that caused some to believe that the transformational-generative model of linguistic theory was a branch of mathematics. In the transformational model, ideas are often described as 'parallel,' 'diametrically opposed,' and 'central.' The fact that Western culture has a predisposition to accept mathematical and scientific models of the world as objective and authentic is another reason

for the switch from structuralism to a generative-transformational model of language.

An essential element of Chomsky's theory of language involves the computer metaphor. Several scholars observed that the computer metaphor is one that prevails when speaking of the mind or brain. Boyd (1979) examined this usage in his analysis of cognitive psychology. Boyd (1979: 360–361) made several equations including the following: (1) thought = information processing; (2) brain language = computations; (3) memory = data storage capacity; and (4) consciousness = feedback. Many of these same analogies exist implicitly in Chomsky's early work such as *Syntactic structures* (1957) and explicitly in his later work *The minimalist program* (1995) where, in fact, his language comes directly from computational jargon. It must also be noted that there are significant differences between the human brain and a computer as well as limitations on both.

Linguistics utilizes theory-constitutive metaphors to elucidate its basic principles. When there are significant changes in these metaphors, there is a paradigm change in the way linguistic theory examines its basic topic of study – language.

Physics Physics uses metaphor to explain and illustrate theories that would otherwise be difficult to comprehend. In his discussion of the metaphoric notion *boojum* (Mermin, 1990), N. David Mermin (b. 1935) points out that this expression derives from Lewis Carroll's (pseudonym of Charles Lutwidge Dodgson, 1832–1898) nonsense poem 'The hunting of the snark.' What Mermin wanted to do was describe the physical properties of a certain type of liquid at very low temperatures. At these low temperatures, the expected patterns could not be maintained, and as was the case with the snark, the physical behavior "softly and suddenly vanished away" (Carroll, 1939: 778). The neologism and the concept are now an established part of physics, as evidenced by its appearance as an entry in *Webster's new international dictionary*. Mermin's use of this metaphor captures the essence of the physical properties of this phenomenon.

Anatomy Sir William Harvey (1578–1657), whose anatomical research revealed the circulation of blood throughout the body, employed a mechanistic metaphor to illustrate his findings. In his description of the auricles and ventricles of the heart, Harvey likened them to the firing of a projectile from a firearm. To be sure, his description is incomplete but compelling.

Second Language Pedagogy Second language pedagogy is replete with metaphoric constructs, many of

them implicit. For Herron (1982), second language methodology consisted of a series of shifting metaphoric models. The grammar-translation model, for example, employs the MIND-BODY metaphor, by which second language acquisition entailed a sort of mental exercise akin to bodybuilding. A second metaphorical model, THE PRODUCTION METAPHOR, was characteristic of audiolingualism. In this approach, the process of imparting a second language to a student is similar to a factory in which a supervisor (instructor) molds the products (students) through their blueprints (textbooks). The basic purpose of this approach was a utilitarian one, in which use of the fundamental language skills (speaking, writing, comprehension, and reading) were the primary goals. The production metaphoric model still lingers in career-oriented classes, i.e., language for specific purposes (medicine, law, social work, and so forth). Herron also noted that a new metaphoric model has emerged; namely, that second language acquisition is the same as first language acquisition. One effect of this metaphor is to make the teacher a parent in the classroom, and this frequently results in a teacher-dominated classroom environment. Metaphoric models, especially unrecognized ones, may have a negative effect on second language instruction because they bear assumptions that may be counterintuitive to the results sought. Danahy (1986) concurred in this assertion and categorized metaphoric models for second language instruction and student-teacher interaction using major divisions – human-non-human metaphors and human-human ones. In the former case, the culinary metaphor entails that an instructor is the actor and the students are the patients. In this active/passive model, students are the recipients of a prepared meal that will enrich and enhance them. In the latter model, the family metaphor is one that assumes that students are child-like individuals incapable of doing anything on their own. This parent-child metaphor is a powerful that prevents students from becoming independent and self-sufficient. Recognition of the metaphoric models that pervade a discipline is essential to an understanding of what we do. Identification of negative or inappropriate conceptual metaphors in any profession is a first step to remedying deficiencies.

Concluding Remarks

In this overview of figurative language, we have seen that there are two basic theories of metaphor: the comparison theory that dates back to Aristotle, and its subsidiary version, the substitution model. In the 20th century, the interactionist theory, originally articulated by I. A. Richards and Max Black, but perhaps most completely developed and elaborated by

George Lakoff and Mark Johnson, provides us with a cognitive-conceptual model of metaphor and its corollaries metonymy and synecdoche to form a novel epistemological model.

Formal Semantics

G Chierchia, Università degli Studi di Milano-Bicocca, Milan, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Semantics, in its most general form, is the study of how a system of signs or symbols (i.e., a language of some sort) carries information about the world. One can think of a language as constituted by a lexicon (an inventory of morphemes or words) and a combinatorial apparatus according to which complex expressions, including, in particular, sentences, can be built up. Semantics deals with the procedures that enable users of a language to attach an interpretation to its arrays of symbols. Formal semantics studies such procedures through formally explicit mathematical means.

The history of semantics is nearly as long and complex as the history of human thought; witness, e.g., the early debates on the natural vs. conventional character of language among the pre-Socratic philosophers. The history of formal semantics is nearly as daunting as it is intertwined with the development of logic. In its modern incarnation, it is customary to locate its inception in the work of logicians such as Frege, Russell, and Tarski. A particularly important and relatively recent turning point is constituted by the encounter of this logico-philosophical tradition with structural and generative approaches to the study of human languages, especially (though by no means exclusively) those influenced by N. Chomsky. The merger of these two lines of research (one brewing within logic, the other within linguistics), has led formal semantics to become a central protagonist in the empirical study of natural language. The research paradigm that has emerged has proven to be quite fruitful, both in terms of breadth and depth of results and in terms of the role it is playing in the investigation of human cognition. The present work reviews some of the basic assumptions of modern formal semantics of natural language and illustrates its workings through a couple of examples, with no pretence of completeness.

Semantics vs. Lexicography

One of the traditional ideas about semantics is that it deals with the meaning of words. The main task of semantics is perceived as the compilation of dictionaries (semantics as lexicography). To this, people often add the task of investigating the history of words. Such a history can teach us about cultural development. One might even hope to arrive at the

true meaning of a word through its history. Compiling dictionaries or reconstructing how particular words have changed over time are worthy tasks; but they are not what formal semantics is about. Lexicography, philology, and related disciplines vs. semantics as conceived here constitute complementary enterprises. They all, of course, deal with language. But the main goal of semantics is to investigate how we can effortlessly understand a potential infinity of expressions (words, phrases, sentences). To do that, we have to go beyond the level of single words.

It may be of use to point to the kind of considerations that have led semantics to move the main focus of investigation away from single word meanings and their development. For one thing, it can be doubted that word histories shed light on how words are synchronically (i.e., at a given point in time) understood and used. People use words effectively in total ignorance of their history (a point forcefully made by one of the founding fathers of modern linguistics, namely F. de Saussure). To make this point more vividly, take the word *money*. An important word indeed; where does it come from? What does its history reveal about the true meaning of money? It comes from Latin *moneta*, the past participle feminine of the verb *moneo* 'to warn/to advise.' *Moneta* was one of the canonical attributes of the Roman goddess Juno; *Juno moneta* is 'the one who advises.' What has Juno to do with money? Is it perhaps that her capacity to advise extends to finances? No. It so happens that in ancient Rome, the mint was right next to the temple of Juno. So people metonymically transferred Juno's attribute to what was coming out of the mint. A fascinating historical fact that tells us something as to how word meanings may evolve; but it reveals no deep link between money and the capacity to advise. This example is not meant to downplay the interest of historical investigations on word meanings; it is just an illustration of how linguistic history affects only marginally the way in which a community actually understands its lexicon.

There is a second kind of consideration suggesting that the scope of semantics cannot be confined to the study of word meanings. Do words in isolation have clearly identifiable meanings? Take any simple word, say the concrete, singular, common noun *dog*. What does it mean? Some possible candidates are: the dog-kind, the concept of dog, the class of individual dogs. . . . And the list can go on. How do we choose among these possibilities? Note, moreover, that all these hypotheses attempt to analyze the meaning of the word *dog* by tacking onto it notions (kind, concept, class . . .) that are in and of themselves in need of

explication. If we left it at that, we wouldn't go far. Looking at dictionary definitions is no big help either. If we look up the entry for *dog*, typically we will find something like:

- (1) A highly variable carnivorous domesticated mammal (*Canis familiaris*) prob. descended from the common wolf.

Indeed, if someone doesn't know the meaning of the word *dog* and knows what *carnivorous* and *mammal* mean, then (1) may be of some practical help. But clearly to understand (1), we must rely on our understanding of whole phrases and the words occurring in them. Words which, in turn, need a definition to be understood. And so on, in a loop. This problem is sometimes called the problem of the circularity of the lexicon. To put it differently, (1) is of help only if the capacity to use and interpret language is already taken for granted. But it is precisely such capacity that we want to study.

The limitation of a purely word-based perspective on the investigation of meaning is now widely recognized. Frege summarized it in a nice motto: "only in the context of a sentence do words have meaning." His insight is that complete sentences are linguistic units that can sort of stand on their own (more so than any other linguistic units). They can, as it were, express self-contained thoughts. We are more likely, therefore, to arrive at the meaning of single words (and of phrases in between words and complete sentences) via a process of abstraction from the contribution that words make to sentence meaning, rather than the other way around. This is so because sentence meaning is somehow more readily accessible (being, as it were, more complete) than the meaning of words in isolation.

These are some reasons, then, why the perspective of modern semantics is so different from and complementary to lexicography and philology; such perspective is much more directly tied to the investigation of the universal laws of language (language universals) and of the psychological mechanisms underlying such laws. Understanding the function, use, etc., of a single word presupposes a whole, complex cognitive apparatus. It is, therefore, an arrival point more than a starting point. It seems thus reasonable to start by asking what it is to understand a sentence.

The main thesis we wish to put forth is that to understand a sentence involves understanding its relations to the other sentences of the language. Each sentence carries information. Such information will be related to that of other sentences while being unrelated to that of yet others. In communicating, we rely on our spontaneous (and unconscious) knowledge of these relations.

The Notion of Synonymy and Its Problems

Imagine watching a Batman movie in which the caped hero fights the Riddler, one of his eternal foes. The Riddler has scattered around five riddles with clues to his evil plans. Batman has managed to find and solve four of them. We could report this situation in any of the following ways:

- (2a) Batman has found all of the five clues but one.
 (2b) Batman has found four out of the five clues.
 (2c) Four of the five clues have been found by Batman.

These sentences are good paraphrases of each other. One might say that they have roughly the same information content; or that they describe the same state of affairs; or that they are (nearly) synonymous. (I will be using these modes of speaking interchangeably.) To put it differently, English speakers know that there is a tight connection between what the sentences in (2a), (2b), and (2c) mean. This is a kind of knowledge they have *a priori*, i.e., regardless of what actually goes on. Just by looking at (2a) vs., say, (2b) and grasping what they convey, we immediately see that they have roughly the same informational content.

This is what we mean when we say that understanding a sentence involves understanding which other sentences count as good paraphrases and which don't. Thus, knowing a language is to know which sentences in that language count as synonymous. Semantics is (among other things) the study of synonymy. Two synonymous sentences (and, more generally, two synonymous expressions) can always be used interchangeably. This last informal characterization can be turned into a precise definition along the following lines.

- (3a) Suppose one utters any complex expression α containing a subexpression A. If one can replace in A α with a different expression β , without changing the overall communicative import of A, then α and β are synonymous.
 (3b) α is synonymous with β = in the utterance of any expression A containing α , α can be replaced with β without changing the communicative import of the utterance (*salva significatione*).

For example, in uttering (2a) (our A), we can replace the subcomponent that comes after *Batman has found*—namely *all of the five clues but one* (our α) with *four out of the five clues* (our β) and convey exactly the same information. Hence, these two expressions must be synonymous (and, in fact, so are the whole sentences).

This looks promising. It paves the way for the following setup for semantics. Speakers have intuitions of whether two expressions can be replaced

with each other while keeping information content unchanged. For any two sentences α and β , they spontaneously know whether they can be substituted for each other (i.e., whether β can be used to paraphrase α). Because the sentences of a language are potentially infinite, it is impossible for speakers to memorize synonymous sentences one by one (for that clearly exceeds what our memory can do). Hence, they must recognize synonymy by rule, by following an algorithm of some sort. The task of semantics, then, becomes characterizing such an algorithm.

There is a problem, however. Sameness of communicative import is a more or less thing, much like translation. In many contexts, even sentences as close as those in (3a) and (3b) could not be replaced felicitously with each other. Here is a simple example. The discourse in (4a) is natural and coherent. The one in (4b) much less so:

- (4a) Batman has found all of the five clues but one,
which is pinned on his back.
(4b) ?? Batman has found four out of the five clues,
which is pinned on his back.
(modeled after a famous example by B. Partee)

Clearly in (4a) we cannot replace *Batman has found all of the five clues but one* with *Batman has found four out of the five clues* while keeping unaltered the overall communicative effect. This means that if we define synonymy as in (3a) and (3b), then (2a) and (2b) cannot be regarded as synonymous after all. Yet they clearly share a significant part of their informational content. What *is* it that they share?

In fact, it has been argued that if (3a) and (3b) are how we define synonymy, then there simply are no two sentences that qualify as such. Here is a classical argument that purports to show this (based on Mates (1950)). Take the following two sentences:

- (5a) Billy has a dog.
(5b) Billy has a highly variable carnivorous
domesticated mammal prob. descended from
the common wolf.

Are these two sentences synonymous? Hardly. They are clearly semantically related. But they surely do not have the same communicative import. Nor can one replace the other in every context. For example, (5a) could describe a true state of affairs, while (5b) might not:

- (6a) Molly believes that Billy has a dog.
(6b) Molly believes that Billy has a highly variable
carnivorous domesticated mammal prob.
descended from the common wolf.

This shows that in contexts like *Molly believes that* — we cannot simply replace a word with its dictionary

definition. And if dictionary definitions don't license synonymy, then what does?

The problem can be couched in the following terms. Any normal speaker of English perceives a strong semantic connection among the sentences in (2a), (2b), and (2c), or (4a) and (4b). So strong that one might feel tempted to talk about synonymy. Yet when we try to make the notion of synonymy precise, we run into serious problems. Such a notion appears to be elusive and graded (a more or less thing); so much so that people have been skeptical about the possibility of investigating synonymy through precise, formal means.

A fundamental breakthrough has been identifying relatively precise criteria for assessing semantic relations. The point is that perfect synonymy simply does not exist. No two sentences can be always replaced with each other. The notion of synonymy has to be deconstructed into a series of more basic semantic relations. We need to find a reliable source for classifying such relations, and, we will argue, such a source lies in the notions of truth and reference. Consider the sentences in (2a), (2b), and (2c) again. Assume that the noun phrase *the five clues* in (2a) and (2b) refer to the *same* clues (i.e., we are talking about a particular episode in a particular story). Then, could it possibly happen that say (2a) is true and (2b) false? Evidently not: no one in his right mind could assert (2a) while simultaneously contending that (2b) is false. If (2a) is true, (2b) also must be true. And, in fact, vice versa: if (2b) is true, then (2a) also must be. When this happens, i.e., when two sentences are true in the same set of circumstances, we say that they have the same truth conditions.

Notice that sameness of truth conditions does not coincide with or somehow require sameness of communicative import (too elusive a notion), nor substitutivity in any context whatsoever (a condition too difficult to attain). Our proposal is to replace such exceedingly demanding notions with a series of truth-based notions, while keeping the same general setup we sketched in connection with synonymy: for any pair of sentences, speakers have intuition about whether they are true under the same conditions or not. They can judge whether they are true in the same (real or hypothetical) circumstances or not. Because the sentences of our language are infinite, this capacity must be somehow based on a computational resource. Speakers must be able to compare the truth-conditions associated with sentences via an algorithm of some sort. The task of semantics is to characterize such an algorithm. The basic notion changes (synonymy is replaced with sameness of truth conditions), but the setup of the problem stays the same.

Truth and Semantic Competence

Let us elaborate on the proposal sketched at the end of the previous section. Information is transmitted from one agent to another (the ‘illocutionary agents’) in concrete communicative situations (‘speech acts’). No two such situations are alike. And consequently, no two pieces of information that are transmitted through them are alike. In *Groundhog Day*, a movie with the actor Bill Murray, the protagonist gets trapped into going through the same day over and over. He wakes up and his day starts out in the same way (with the alarm clock ringing at 7 a.m. on groundhog day); as he walks outside, he meets the same waitress who greets him in the same way (“weather so-so, today”). Yet this sentence, though being the same day after day, and being uttered in circumstances as identical as they can conceivably be, clearly conveys a different sense or information unit on each occasion of its use (the hearer going from noticing that something is fishy about this verbatim repetition, to the painful discovery of the condemnation to live through groundhog day for eternity).

Ultimately, we want to understand how communication takes place. But we cannot nail down every aspect of a speech act, just as we cannot know (not even in principle, I believe) every aspect of the physical or mental life of a particular human being. At the same time, while speech acts are unique events, there is much that is regular and invariant about them; that is what can be fruitfully investigated. One family of such invariants concerns form: similar sound patterns may be used in different speech acts. Another family of invariants concerns content: similar states of affairs may be described through a variety of expressions. The notion of truth is useful in describing the latter phenomenon. A pair of sentences may be judged as being necessarily true in the same circumstances. This is so, for example, for (5a) vs. (5b). Yet, such sentences clearly differ in many other respects. One is much more long-winded than the other; it uses rarer words, which are typical of high, formal registers. So in spite of having the same truth conditions, such sentences may well be used in different ways. Having the same truth condition is generally regarded as a semantic fact; being able to be used in different ways is often regarded as a pragmatic fact. While this gives us a clue as to the role of these two disciplines (both of which deal with meaning broadly construed), the exact division of labor between semantics and pragmatics remains the object of controversy.

Truth conditions are a tool for describing semantic invariants, structural regularities across communicative situations. Whenever I utter a declarative sentence, I typically do so with the intention to

communicate that its truth conditions are satisfied (which of course raises the question of nondeclaratives, emotive expressions, and the like; see for example textbooks such as Chierchia and McConnell-Ginet (2000) or Heim and Kratzer (1998); cf. also Kratzer (1999) for a discussion of relevant issues). Truth conditions depend on the reference (or denotation) of words and the way they are put together, i.e., they are compositionally projected via the reference of words (or morphemes). If I say to you, as we are watching a movie, “Batman has found all of the five clues but one,” you understand me because you sort of know (or guess) who Batman is, what sort of things clues are, what finding something is, what number the word *five* refers to; you also understand the “all ... but ...” construction. The reference/denotation of words is set (and is modified, as words may change their denotation in time) through use, in complex ways we cannot get into within the limits of the present work. The denotation of complex expressions (e.g., of a verb phrase such as [_{VP}found five clues] and truth conditions of sentences) are set by rule (the semantic component of grammar). Semantic rules presumably work like syntactic rules: they display variation as well as a common core, constitutive of universal grammar. Insofar as semantics is concerned, what is important for our purposes is that truth conditions can be compositionally specified. This paves the way for an algorithmic approach to meaning. We already remarked that sentences are formed by composing morphemes together via a limited number of syntactic operations. So to arrive at the truth condition of an arbitrary sentence, we can start by the contribution of the words (their reference). Then, for each way of putting words together, there will be a way of forming the reference of complex expressions, and so on until we arrive at the truth condition of the target sentence.

So far, we have discussed sentences that have the same truth conditions (such as those in (2a), (2b), and (2c)); but this is not the only semantic relation that can be characterized in terms of the notion of truth. Consider the following examples.

- | | |
|--------------------------|-------------------------|
| (7a) Every Italian voted | a'. Most Italians voted |
| for B | for B. |
| (7b) Leo voted for B | b'. Leo voted for B. |

Sentence (7a) is related to (7b) in a way that differs from the relation between (7a') vs. (7b'). Here is the difference. If (7a) is true, and Leo is Italian, then (7b) has to be true, too; this is clearly not so for (7a') vs. (7b'): (7a') may be true without (7b') being true. If whenever A is true, B also must be, we say that A *entails* B (B's meaning is part of A's meaning). Two sentences with the same truth conditions entail

each other (i.e., they hold a symmetric relation); when entailment goes only one way (as from (6a) to (6b)), we have an asymmetric relation.

Entailment is pervasive. Virtually all semantic intuitions are related to it. As an illustration, consider the pair of sentences in (8a) and (8b).

- (8a) John promised Bill to take him to the station.
- (8b) John ordered Bill to take him to the station.

Pronouns, like *him* in (8a) and (8b), take their denotation from the context; they can take it from the extra linguistic context (a person salient in the visual environment, a person the speaker points at, etc.) or from the linguistic context (e.g., from NPs that occur in the same discourse; *John* or *Bill* in (8a) and (8b)); one widespread terminology is to speak of *indexical* uses in the first case and of *anaphoric* uses in the second. We can conceptualize this state of affairs by viewing pronouns as context-dependent items, incomplete without pointers of some sort. Now we shall focus on the anaphoric interpretation of (8a) vs. (8b).

- (9a) John promised Bill that John would take Bill to the station.
- (9b) John ordered Bill that Bill should take John to the station.

These appear to be the only options. That is to say, sentence (8a) cannot convey something like 'John promised Bill that Bill should take John to the station.' The point of this example is that we have intuitions that govern how the denotation of a pronoun is to be reconstructed out of contextual clues; such intuitions tell us that (8a) and (8b), though structurally so similar, allow for a distinct range of interpretive options. At the basis of intuitions of this sort, we again see entailment at work: on its anaphoric construal, (8a) entails (9a).

Another important set of truth-based semantic relations are presuppositions. Consider the contrast between the sentences in (10a) and (10b).

- (10a) Fred stole the cookies.
- (10b) It was Fred who stole the cookies.

There is a noticeable semantic contrast between (10a) and (10b). How can we characterize it? Clearly the two sentences are true in the same circumstances (they entail each other). Yet they differ semantically. Such a difference can be perhaps caught by looking at what happens by embedding (10a) and (10b) in a negative context.

- (11) So, what happened this morning?
- (11a) Everything went well. Fred didn't steal the cookies; he played with his toys.
- (11b) ?? Everything went well. It wasn't Fred who stole the cookies.

The answer in (11a) is natural. The one in sentence (11b) would sound more natural as an answer to

- (12a) Who stole the cookies?
- (12b) It wasn't Fred.

The difference between the question in (11) and the one in (12a) is that the latter (but not the former) tends to presuppose that cookies were stolen. In other terms, the situation seems to be the following. Both sentences in (10a) and (10b) entail:

- (13) Someone stole the cookies.

If either (11a) or (11b) are true, then (13) must also be true. Furthermore, sentence (13) must be true for (10b) to be *denied* felicitously. The illocutionary agents must take for granted the truth of (13) to assert, deny, or otherwise use sentence (10b), as the naturalness of the following continuations for (13) illustrate:

- (14) Someone stole the cookies ...
- (14a) It was Fred.
- (14b) It wasn't Fred.
- (14c) Was it Fred?
- (14d) If it was Fred, he is going to get it ...

This brings us to the identification of presupposing as a distinctive semantic relation: a sentence A presupposes B if the truth of B must be taken for granted in order to felicitously assert, deny, etc., A. Presuppositions are quite important in language. So much so that there are distinctive syntactic constructions (such as those in (10b), known as cleft sentences) specifically keyed to them.

Let me illustrate the wealth of semantic relations and their systematic character by means of another example, which will bring us to the interface between semantics and pragmatics. Consider:

- (15a) Who stole the cookies?
- (15b) Fred looks mischievous.
- (15c) Fred stole the cookies.

If to a question such as (15a), I reply with (15b), I do suggest/convey something like (15c). Sentence (15c) clearly is not part of the literal meaning of (15b) (however hard defining such a notion might be). Yet, in the context of the dialogue in (15a), (15b), and (15c), speakers will converge in seeing that (15c) is strongly suggested by (15b). Here, too, we have, thus, a systematic semantic intuition. The suggestion in (15c) can be retracted; that is, one can continue (15b) with '... but I know he didn't do it'. However, in the absence of such an explicit correction, illocutionary agents upon hearing (15b) will tend to infer (15c). This phenomenon has been studied by H. P. Grice (1989), who dubbed it implicature. His

proposal is that it arises through interaction of the core meaning assigned to sentences by rule with principles that govern conversational exchanges. The basic idea is that for conversational exchanges to be successful they have to be basically cooperative acts; cooperating means that one sticks to relevant topics, one only gives information believed to be truthful, one gives no more and no less than what is relevant, etc. Applying this to the case at hand, in a situation in which question (15a) is topical, answering (15b) would seem to be blatantly irrelevant; the hearer, however, tends to interpret it as relevant and sets in motion an inferential process that tends to link it to some piece of information that does address the topical question; such a link is to be found with the help of the information available in the context to the illocutionary agents (e.g., in the common knowledge that if people commit a mischief, such as stealing cookies, they may well look mischievous, etc.). Thus, this type of semantic judgment (the implicature) appears to be best accounted for in terms of the interaction between grammar and general conditions on reasonable language use (that fall under the scope of pragmatics).

Sometimes it is not immediately clear whether something is a matter of conventionalized meaning or pragmatics. To illustrate, consider the oscillation in meaning of a word like *or*. It can be illustrated with the following examples. Consider first (16a):

- (16a) If I got it right, either John or Mary will be hired.
- (16b) If I got it right, either John or Mary but not both will be hired.

Normally, one tends to interpret (16a) as truth conditionally equivalent to (16b); i.e., the disjunction in (16a) is interpreted exclusively (as incompatible with the simultaneous truth of each disjunct). However, this is not always so. Contrast (16a) with (17a).

- (17a) If either John or Mary are hired, we'll celebrate.
- (17b) (?) If John or Mary (but not both) are hired, we'll celebrate.
- (17c) If John or Mary or possibly both are hired, we'll celebrate.

The most natural interpretation of (17a) is not the exclusive one (namely (17b), which is somewhat odd pragmatically); rather it is the inclusive one, made explicit in (17c). (Notice that the emphatic word *either* is present both in (16a) and (17a); in spite of this, the interpretation of *or* shifts.) We might see in these phenomena a lexical ambiguity of disjunction. Words expressing disjunction, we may feel inclined to conclude, have a varying interpretation, as it happens

with words such as *bank* or *lap* ('sit on my lap' vs. 'he swam three laps'). We may assume that such interpretations are always in principle available, but then we select the most suitable to the context of the speech act. While this seems *prima facie* possible, there are reasons to doubt it. In particular, true lexical ambiguities are resolved across languages (in Italian, there are two different words for the two senses of *lap*). Ambiguities are never universal. The meaning shift of *or*, *per contra*, seems to be universal: in every language disjunction appears to have a similar oscillation in meaning. A convincing case for two lexically distinct disjunctions, one exclusive, the other exclusive, has not been made (sometimes it has been proposed that Latin *vel* vs. *autem* is just that; for arguments against this, cf., e.g., Jennings (1994)). Moreover, other areas of the lexicon have been found that display a similar behavior (e.g., the number words). This strongly suggests that a different explanation for such behavior should be found. Grice himself has proposed that the phenomenon under discussion is to be accounted for in terms of the interaction between semantics and pragmatics. The idea is that the basic meaning of *or* is the inclusive one, as it is the most liberal interpretation; the exclusive construal arises as an implicature, i.e., a pragmatic enrichment, albeit a generalized one. The advantage of this move is that it would explain the oscillation in meaning of disjunction without positing a covert ambiguity. We will come back to how the generalized implicature associated with *or* might come about in the later section "The Semantics/Pragmatics Interface".

Wrapping up, the picture that emerges is roughly the following. In using language, speakers display complex forms of spontaneous knowledge. They put together words in certain ways and not others. This is how knowledge of syntax manifests itself. They also accept certain paraphrases and not others, draw certain inferences and not others, etc. It turns out to be possible/useful to categorize the latter in three major families of semantic relations.

- (18a) Entailment-based (entailment, mutual entailment, contradictoriness, analyticity, etc.)
- (18b) Presupposition-based (presupposition, question/answer pairs, etc.)
- (18c) Implicature-based (generalized implicature, particularized implicature, etc.)

All of them can be readily defined in terms of the notion of truth:

- (19a) A entails B = for any conceivable situation *s*, if A is true in *s*, B is also true in *s*.

- (19b) A presupposes B = to use A appropriately in a situation *s*, the truth of B must be taken for granted by the illocutionary agents in *s*.
 (19c) A implicates B = use of A in a situation *s* suggests, everything else being equal, that B is true in *s*.

The definitions in (19a), (19b), and (19c) can be readily associated with “operational” tests that enable speakers to assess whether a given relation obtains or not. For example, to check whether (20a) entails (20b), you might check whether you could sincerely assert (20a) while denying (20b), viz. whether you could sincerely and felicitously utter something like (20c):

- (20a) It is indeed odd that Mary is home.
 (20b) Mary is home.
 (20c) It is indeed odd that Mary is home, even if she in fact isn't.

To the extent that you can't really say something like (20c), you are entitled to conclude that (20a) entails (20b). It is useful, in these cases, to use contrast sets such as (21a) and (21b).

- (21a) It is indeed conceivable that Mary is at home.
 (21b) It is indeed conceivable that Mary is home, even if she in fact isn't.

The semantic relations in (18a), (18b), and (18c) can be viewed as intuitions of semantic relatedness speakers have about sentences of their own language, as judgments that may be elicited, and the like. By analogy with well-formedness judgments, there are some cases in which things are not so clear and we may not be sure whether, say, a certain entailment holds or not. In such a case, more complex arguments, indirect evidence of various sorts, or psycholinguistic experimentation may be called for (see, e.g., Crain and Thornton (1998) on experimental methodologies for truth-based semantic judgments). But in indefinitely many cases, simple introspection yields relatively straightforward judgments. The capacity for making such judgments is constitutive of our semantic competence. Such a competence cannot be simply a thesaurus, a store of pairs of sentences, with the relative judgment tacked on, for the number of judgments speakers can make on the fly is potentially infinite. Semantic competence must be a computational device of some sort. Such a device given an arbitrary pair of sentences $\langle A, B \rangle$ must be able to determine in principle whether A entails B, presupposes it, etc. The task of semantics is to characterize the general architecture of such a computational device. While there are many foundational controversies that permeate the field, there is a broad convergence that this is roughly the

form that the problem of meaning takes within modern formal semantics.

Semantic Modeling

In the present section I will sketch how a (necessarily, much simplified) calculus of semantic relations may look. Suppose you have a lexicon of the following form:

- (22a) N: John, Bill, dog, cat, table, . . .
 (22b) V: runs, smokes, drinks, . . .
 (22c) DET: the, a, some, every, no . . .

Think of syntax as a device that combines lexical entries by merging them in complex phrases and assigning them a syntactic analysis that can be represented by tree diagrams or labeled bracketings of the following form:

- (23a) [_{VP} John smokes]
 (23b) [_{DP} every boy]
 (23c) [_{VP} [_{DP} every boy] smokes]

I assume, without being able to justify it, that lexical items have phrasal projections. In particular, VP is the phrasal projection of V and constitutes a clausal nucleus composed of the verb and its arguments linked in a predicative structure. Such a nucleus forms the innermost skeleton of the sentence (I will have to ignore matters pertaining to inflection, agreement, tense, and the like). The lexical features of verbs are crucial in determining the characteristics of clausal nuclei. DP is the phrasal projection of D, and it is constituted by a determiner and a (common) noun. Clausal nuclei can be formed by merging a verb with a (proper) name or a DP, as indicated. In the spirit of the discussion in the section on **Truth and Semantic Competence**, semantics assigns recursive truth conditions to sentences in terms of the reference assigned to lexical entries. There are several ways to do this. Ultimately, the choice one makes on the exact format of interpretive rules has far-reaching consequences for our understanding of grammar. However, our choices here are only in small part dictated by our current understanding of semantics in universal grammar; for the major part, they result from considerations such as ease of exposition, keeping prerequisites at a minimum, and the like. To get started, we should assign a reference (or denotation, terms we will use interchangeably) to lexical entries. To do so, we assume we have a certain domain $D_s = \{a, b, c, \dots\}$ at each given discourse situation *s* that constitutes our universe of discourse. A discourse situation can be thought of as the time at which the utterance takes place. A domain is just a set of individuals,

pragmatically selected (e.g., those salient to the illocutionary agents). Interpretations are relative to an utterance situation s and the corresponding domain of discourse D_s . Reference of proper nouns, for example, is suitably chosen from the domain of discourse. Suppose, for example, that a and b are salient humans in our universe of discourse, then we might have:

- (24) For any conceivably relevant utterance situation s , the name *John* denotes a in s ; the name *Bill* denotes b in s ...

It doesn't matter how a or b are characterized (via a description, an act of indication, etc.) to the extent that one successfully succeeds in linking the noun to its bearer. Also, it is useful to have a uniform category-neutral notation for semantic values; we will use for this the double bar notation $\| \cdot \|$; accordingly, for any expression α , $\|\alpha\|^s$ will be the semantic value of α in situation s . Thus, (24) can be abbreviated as:

- (25) $\|John\|^s = a$ (where $a \in D_s$, the domain of discourse at s)

(Technically, $\| \cdot \|$ can be viewed as a function from expressions and situations into denotations; so sometimes we will speak of the interpretation function.) The denotation of a simple (intransitive) verb such as those in (22b) can be thought of as a function that for each (appropriate) individual in the domain discourse tells us whether that individual performs a certain action or not. Here is an example:

- (26) *smokes* in a situation s denotes a function smoke_s that applies to animate individuals and returns truth values. If a is such an individual, then $\text{smoke}_s(a)$ returns 'true' (which we represent as the number 1) if that individual performs the action of smoking in s (where smoking involves ...); otherwise $\text{smoke}_s(a)$ returns 0 (i.e., 'false').

If a is not animate (e.g., if a is a stone and s is a 'normal' situation), then $\text{smoke}_s(a)$ is not defined (lacks a value). The final part in definition (26) reflects the fact that sentences like (27a) and (27b), out of the blue, are (equally) strange: smoking normally requires its subject argument to be animate.

- (27a) That stone smokes.
(27b) That stone doesn't smoke.

The deviance of sentences like (27a) and (27b) has been variously characterized as a violation of selectional restrictions or as sortal deviance. Here we are couching the relevant phenomenon in presuppositional terms (to illustrate a further application of such a concept). The fact that sentences of this sort remain deviant across negation may be taken as

evidence that the verb *smoke* imposes an animacy presupposition on its arguments (see e.g., Chierchia and McConnell-Ginet (2000) for more discussion). A definition like (26) can be stated more compactly:

- (28) $\|\text{smokes}\|^s = \text{smoke}_s$,
where for each a in D_s , $\text{smoke}_s(a)$ is defined iff a is animate in s ; if defined, $\text{smoke}_s(a) = 1$ if a smokes in s (where smoking involves ...);
 $\text{smoke}_s(a) = 0$, otherwise.

The definition of (or constraints on) smoking (i.e., the dots in (28)) can be elaborated further in several ways by refining our lexical analysis of the verb *smoke*. Although much progress has been made on this score, many important issues remain open (including, e.g., whether a presuppositional treatment of selectional restrictions is ultimately viable). What is important, from the point of view of compositional semantics, is the *logical type* or *semantic category* of the denotation of a verb like *smoke*. Such verbs are treated here as functions from individuals into truth values. These are called *characteristic functions*; they divide the (relevant portion of) the domain of discourse of the utterance situation in two: the things that satisfy the verb from those that don't. Characteristic functions correspond to sets (which might be called the *extension* of the function), as the following example illustrates:

- (29) Let universe of discourse be $\{a, b, c, d\}$; let a, b , and c be people. Of these, let a and b smoke in s while b but not a also smokes in a different situation s' . We can represent all this as follows:
- | | |
|---------------------------------------|-------------------------------------|
| $a \rightarrow 1$ | |
| $\text{smoke}_s = b \rightarrow 1$ | corresponding extension: $\{a, b\}$ |
| $c \rightarrow 0$ | |
| $a \rightarrow 1$ | |
| $\text{smoke}_{s'} = b \rightarrow 0$ | corresponding extension: $\{a\}$ |
| $c \rightarrow 0$ | |

As is evident from the example, sets and characteristic functions are structurally isomorphic (encode the same information). In what follows it will be useful on occasion to switch back and forth between these two concepts. Use of characteristic functions as a formal rendering of verb meanings is useful in giving truth conditions for simple subject predicate sentences:

- (30a) A sentence of the form $[_{VP} N V]$ is true in s iff $\|V\|^s (\|N\|^s) = 1$
Example:
(30b) $[_{VP} \text{Bill drinks}]$ is true in s iff $\|\text{drinks}\|^s (\|\text{Bill}\|^s) = 1$

The truth conditions of any sentence with the syntactic structure specified in (30a) boil down to applying a

characteristic function to an individual (and thereby ascertaining whether that individual belongs to the set that constitutes the extension). To find out whether Bill in fact smokes in *s*, we need factual information about the situation obtaining in *s*. To understand the sentence, we don't. We merely need to know its truth conditions, which in the case of simple subject-predicate sentences are an instruction to check the value of a characteristic function for the argument specified by the subject. The rules in (30a) and (30b) can be reformulated more compactly as in (31):

$$(31) \llbracket [_{VP} N V] \rrbracket^s = \llbracket V \rrbracket^s (\llbracket N \rrbracket^s)$$

This can be viewed as the kernel of a predication rule (that tells us how subject and predicates combine semantically).

Everything so far looks like a formally explicit (and perhaps somewhat pedantic) way of sketching a denotational, information-oriented semantics, and the reader may get the feeling of not yet finding striking insights on what meaning is. In order to grasp the potential of this method, one needs to look at a little more of its computational apparatus. So let us turn now to DPs. Things here are definitely more challenging. DPs are constituents formed by a determiner plus a common noun. Common nouns can be given, at least in first approximation, the same analysis as (intransitive) verbs, i.e., the meaning of, say, *cat* can be thought of as a characteristic function that selects those entities that are cats out of the universe of discourse (or, equivalently, we can say that *cat* identifies a class/set across situations). But what about things like *no cat* or *every cat*, which are the typical constituents one finds in, e.g., subject position and the like? What does *no cat* denote? And, even worse, what do *no* or *every* or *some* denote? Our program is to assign a denotation to lexical entries and then to define in terms of it truth conditions for sentences. So we must find suitable denotations of Ds and DPs.

To address questions of this sort, we apply a heuristic that goes naturally with our general setup: whenever the denotation of an expression is not directly accessible to your intuition, look at what that expression contributes to the truth conditions of the sentences it occurs in (the epistemological primacy of sentences, again). So, consider for example:

(32) No boy smokes.

We know/assume/conjecture that *boy* and *smoke* denote characteristic functions and that sentences contribute truth values (i.e., they are true or false, as the case may be, in different situations). We may think of *no* as a function, too. As is evident from

(32), such a function combines first with a characteristic function/set (corresponding to the noun); then the result combines with a second characteristic function (corresponding to the verb) to yield a truth value. Schematically, here is what we have:

$$(33) \text{no}(\text{boy}_s) (\text{smoke}_s) = 1 \text{ or } 0$$

Now we can look at our intuitions. When is (32) true? The answer is pretty clear. When among the boys, nobody smokes. Or, equivalently, when the class of boys (i.e., the extension of *boy_s*) has no member in common with the smokers (i.e., the extension of *smoke_s*), (32) is true. In set talk, the intersection between the boys and the smokers must be empty:

$$(34) \text{no}(\text{boy}_s) (\text{smoke}_s) = 1 \text{ iff } \text{BOY}_s \cap \text{SMOKE}_s = \emptyset$$

(where *BOY_s*, *SMOKE_s* are the extensions corresponding to *boy_s*, *smoke_s*, respectively) This is perfectly general. Replace boy/smokes with any other noun/verb. The contribution of *no* stays constant: *no*(*N*) (*V*) is true just in case no member of the extension of *N* is in *V*. We thus discover that *no* has a perfectly sensible (if abstract) denotation: a function that encodes a relation between sets. Our contention here is that speakers behave as if they had such a function in mind (or something similar to it) in using *no*.

The next step is to see that *all* determiners express relations among sets (characteristic functions), just like *no* does. Here are a few examples, along with some comments.

(35a) *Some*

(35a.i) Example: some boy smokes

(35a.ii) Truth conditions: *some*(*boy_s*) (*smoke_s*) = 1 iff *BOY_s* ∩ *SMOKE_s* ≠ ∅

(35a.iii) Comment: *some* is the contrary of *no*; *some boy smokes* is true just in case you can find someone among the boys who is also among the smokers; i.e., the intersection between the class of boys and the class of smokers must be non empty. The indefinite article *a* can be analyzed along similar lines.

(35b) *Every*

(35b.i) Example: every boy smokes

(35b.ii) Truth conditions: *every*(*boy_s*) (*smoke_s*) = 1 iff *BOY_s* ⊆ *SMOKE_s*

(35b.iii) Comment: *every* expresses the subset relation: *every boy smokes* is true just in case all the members of the class of boys also belongs to the class of smokers

(35c) *Most*

(35c.i) Example: Most boys smoke

(35c.ii) *most*(*boy_s*) (*smoke_s*) = 1 iff the number of member of *BOY_s* ∩ *SMOKE_s* is

bigger than half the number of members of BOY_s .

- (35c.iii) Comment: *most* involves actual counting. *Most boys smoke* is true just in case the number of boys who smoke (i.e., the intersection of the boys with the smokers) is greater than half the number of boys (i.e., more than half of the boys are smokers).

(35d) *The*

- (35d.i) Example: The blond boy smokes.

- (35d.ii) Truth conditions: $\text{the}(\text{blond boy}_s)(\text{smoke}_s)$ is defined only if there is exactly one blond boy in s . Whenever defined, $\text{the}(\text{boy}_s)(\text{smoke}_s) = \text{every}(\text{boy}_s)(\text{smoke}_s)$.

- (35d.iii) Comment: this reflects the fact that *the blond boy smokes* is only interpretable in situations in which the universe of discourse contains just one blond boy. If there is more than one blond boy or if there is no blond boy, we wouldn't really know what to make of the sentence. So *the* is a presuppositional determiner; it presupposes the existence and uniqueness of the common noun extension. (This analysis of *the* goes back to Frege.)

In spite of the sketchiness of these remarks (that neglect important details of particular determiners), it should be evident that the present line of analysis is potentially quite effective. A class of words and phrases important and tendentially stable across many languages falls into place: determiners ultimately express natural relations between sets (the set associated with the common noun and the set associated with the verb phrase). Our denotational perspective seems to meet rather well the challenge that seemingly denotationless items pose. It is useful to see what becomes of our rule of predication (viz. (31) above). Evidently such a rule needs to be split into two (main) subcases, depending on whether the subject is a simple N (a proper name) or a complex DP. Here is an exemplification of the two cases:

(36a) Mary smokes.

(36b) No boy smokes.

In case (36a), we have semantically two pieces: an individual (whomever *Mary* denotes) and a characteristic function (smoke_s); so the latter applies to the former. In case (36b) the two pieces are: a complex function (namely $\text{no}(\text{boy}_s)$) that looks for a characteristic function to yield a truth value, and, as before, the characteristic function smoke_s ; in this case the former applies to the latter. In either case, the end result is a truth value. So our predication rule becomes:

(37a) $\| [\text{VP N V}] \|^\S = \|\text{V}\|^\S (\|\text{N}\|^\S)$

(37b) $\| [\text{VP DP V}] \|^\S = \|\text{DP}\|^\S (\|\text{V}\|^\S)$

This suggests that the core rule of semantic composition is functional application. Consider for example an ungrammatical sentence of the form:

(38) * $[\text{VP boy smokes}]$

Such a sentence, as things stand, would be generated by our (rudimentary) syntax. However, when we try to interpret it, we find two characteristic functions of individuals, neither of which can apply to the other. Hence, the sentence is uninterpretable, which explains its ungrammaticality. There are languages like, for example, Russian or Hindi where singular common nouns without a determiner can occur in subject position:

(39a) Russian: mal'cik kurit boy smokes 'the boy smokes'

(39b) Hindi: kamre meN cuuha ghuum rahaa hai (from Dayal 2004) room in mouse moving is 'a mouse is moving in the room'

Notice that (39a) is the verbatim translation of (38) and is grammatical in Russian. The line we are taking suggests that in such languages it must be possible to turn some covert forms of common nouns into argumental DPs, i.e., things that can semantically combine with predicates; for example it is conceivable that in a language without articles, like Russian, the semantic functions associated with the articles can be applied covertly (as part of the interpretive procedure), so as to rescue the semantic mismatch that would otherwise ensue. This may, in turn, involve the presence of a phonologically null determiner (for alternative developments of this line of analysis, as well as details concerning the available interpretations, see, e.g., Chierchia (1998), Longobardi (2001), and Dayal (2004)).

The picture that emerges is the following. The basic mode of syntactic composition is *merge*, or some analogously simple operation that puts together two constituents (subject to parametrization pertaining to, e.g., word order, case, etc.). The basic mode of semantic composition is *apply*: constituents are compositionally analyzed as functions (of more or less complex semantic type) and arguments (individuals or other functions); so whenever we find a function and an argument of the appropriate sort, we simply apply the former to the latter. If things go wrong at any level, the derivation crashes and the result is ungrammatical. The semantic side of this process has come to be known as 'type driven interpretation,' the main idea being that the semantic categories of functions and arguments drive the interpretation process.

The present approach directly yields a computationally tractable theory of entailment and presupposition.

We have defined entailment roughly as follows: a sentence *S* entails a sentence *S'* iff whenever *S* is true, *S'* is also true. The apparatus we have developed allows us to prove whether a certain entailment holds or not. Let me show, as an illustration, that (40a) entails (40b) but not vice versa.

- (40a) Every scientist smokes.
- (40b) Every mathematician smokes.

To show this we need to assume that if one is a mathematician, one is a scientist; i.e.,

- (41) For every individual *a*,
- (41a) if **mathematician**_s (*a*) = 1, then **scientist**_s (*a*) = 1 or, equivalently:
- (41b) **MATHEMATICIAN**_s ⊆ **SCIENTIST**_s

Consider now the semantics of (40a), according to our analysis. It is the following:

- (42) **every**(**scientist**_s) (**smoke**_s)

In virtue of (35b), this is tantamount to

- (43) **SCIENTIST**_s ⊆ **SMOKE**_s

This being so, every subset of the set of scientists must also be included among the smokers (by elementary set theoretic considerations). Since, in particular, mathematicians are scientists, it follows that

- (44) **MATHEMATICIAN**_s ⊆ **SMOKE**_s

But this is just the semantics of (40b). So, if (40a) is true in *s*, then (40b) must also be true in *s*. Evidently, this reasoning goes through no matter which situation we are in. Hence, (40a) does entail (40b). On the other hand, it is easy to conceive of a situation in which (44), and hence (40b), hold, but say some economist doesn't smoke; in such a situation, (43) would fail to obtain. Hence, (40b) does not entail (40a).

A fully parallel way of reasoning can be put forth for presuppositions. We said that *S* presupposes *S'* iff *S'* must be taken for granted in every situation in which *S* is asserted, denied, etc. This can be cashed in as follows. We can say that for *S* to be true or false (i.e., to have a semantic value that makes it suitable for assertion or denial), *S'* must be known to be true in the utterance situations by the illocutionary agents, i.e., *S* can be true or false in *s* iff *S'* is true in *s*. Using this definition (known as the 'semantic' definition of presupposition), we can formally prove (though we will not do so here) that, for example, (45a) presupposes (45b):

- (45a) The blond boy smokes.
- (45b) There is exactly one blond boy around.

The general point of these examples is the following. Intuitions about entailment and the like are

a priori; speakers have them just by inspecting the meaning of the relevant sentences. In the present setup, this central fact is captured as follows. Semantics can be viewed as a set of axioms that (a) determines the interpretation of lexical entries and (b) assigns truth conditions to sentences. Such apparatus yields a calculus of entailment (and other semantic relations) that reemerge as theorems of semantics. We have not formalized each single step of the derivation (relying on the readers' patience and understanding of elementary set theory); but such a formalization is, evidently, feasible. We not only thereby gain in clarity. We also obtain a device that constitutes a reasonable (and falsifiable) model of speakers' linguistic abilities. The claim is not that the specific rules we have given are actually implemented in the speakers' mind. The claim is that speakers, to the extent that they can be said to compute entailments must be endowed with computational facilities that bear a structural resemblance to the ones sketched here. This, in turn, paves the way for inspecting the architecture of our linguistic abilities ever more closely. Without excessive optimism and in full awareness of the controversies that permeate the field, this seems to constitute a step in the right direction.

One further remark on the general picture that emerges from the sketch above cannot be avoided. Our approach to meaning is denotational: we assign a denotation to words and morphemes and (in terms of such denotations) truth conditions to sentences. This can be understood in several ways, of which I will present two much simplified extremes. We can take truth condition assignment as a way of exposing the link between language and the world, which is, arguably, the ultimate goal of semantics. Words/morphemes are actually mapped into aspects of the world (e.g., names are mapped into actual individuals); sentences are symbolic structures that code through their fine structure how things may be arranged in the world. However, it is also possible to view things somewhat differently. What really matters, it can be argued, is not the actual mapping between words and aspects of reality and between sentences and the conditions under which they, in fact, are true. What we do is give a form or recipe or potential for actual truth conditions; we merely constrain the form that truth conditions may take. What we get out of this is what really matters: a calculus of semantic relations (entailment, presupposition, etc.). Unlike what happens in, say, pure logic, such a calculus is not a normative characterization of sound reasoning; it is an empirically falsifiable characterization of semantic competence (i.e., of what speakers take to follow from what, when). Under

the latter view, truth conditions (or truth condition potentials, or whatever it is that we map sentences on) are a ladder we climb on to understand the working of semantic relations, i.e., relations that concern the information content of linguistic expressions.

It is evident that we are not going to settle these issues here. As a small consolation (but also, if you wish, as evidence of the maturity of the field), I hope to have given the reader reasons to believe that progress is possible even if such foundational issues remain open.

We haven't discussed implicatures and other pragmatically driven intuitions about meaning. To understand the full scope of the present proposal, it is important to do so. This requires extending a bit what we have done so far.

The Semantics/Pragmatics Interface

In the section **Truth and Semantic Competence**, we mentioned implicatures, a broad and varied type of meaning relations. We will elaborate by looking more closely at the oscillation in the meaning of *or*. The purpose is to illustrate how generalized implicatures come about and how this bears on the view of semantics sketched in the preceding section on **Semantic Modeling**.

The first step is to attempt a semantic analysis of *or*. To this we now turn. Imagine we extend our grammar by introducing coordination and negation along the following lines:

- (46a.i) $[_{VP} \text{ John doesn't smoke}]$
- (46a.ii) $[_{VP} \text{ NEG VP}]$
- (46b.i) $[[_{VP} \text{ John smokes}] \text{ and/or } [_{VP} \text{ Bill smokes}]]$
- (46b.ii) $[_{VP} \text{ and/or VP}]$

The syntax of negation and coordination poses many thorny questions we simply cannot address here. Although for our purposes any number of assumptions concerning syntax might do, let us maintain, again without much justification, that a negative sentence like (46a.i) has the structure in (46a.ii) out of which the observed word order is derived by moving the subject left from the inner VP. Furthermore, we will assume that coordinated sentences, whether disjunctive or conjunctive, such as (46b.i), are obtained through schemas such as (46b.ii). Insofar as semantics is concerned, the introduction of negation, conjunction, disjunction, etc., poses problems similar to that of determiners. The relevant expressions are function words, and it is not obvious how to analyze them in denotational terms. This question, however, can be addressed in much the same way as we have done with the determiners: by looking at what the relevant elements contribute to the truth conditions of the

sentences they occur in. For sentential operators, we can draw on a rich logical tradition. In the attempt to characterize the notion of valid inference, logicians have discussed extensively propositional connectives (like *not*, *and*, *or*), and the outcome is an analysis of such elements as truth functions or, equivalently, in terms of 'truth tables.' For example, the contribution of negation to meaning can be spelled out in terms of conditions of the following sort:

- (47a) *John doesn't smoke* is true in s iff *John smoke* is false in s

- (47b) $\| \text{NEG VP} \|_s = 1$ iff $\| \text{VP} \|_s = 0$

(47c)	VP	NEG VP
	1	0
	0	1

In (47c) we display in the form of a truth table the semantics given in (47b). Essentially, this says that in uttering a negation like (47a), the speaker intends to convey the falsity of the corresponding positive sentence. By the same token, conjunctions can be analyzed as in (48a), (48b), and (48c), and disjunction as in (49a), (49b), and (49c):

- (48a) *John smokes and Bill smokes* is true if both *John smokes* and *Bill smokes* are.

- (48b) $\| [VP_1 \text{ and } VP_2] \|_s = 1$ iff $\| VP_1 \|_s = \| VP_2 \|_s = 1$

(48c)	VP ₁	VP ₂	$[VP_1 \text{ and } VP_2]$
(48c.i)	1	1	1
(48c.ii)	1	0	0
(48c.iii)	0	1	0
(48c.iv)	0	0	0

- (49a) *John smokes or Bill smokes* is true if either *John smokes* or *Bill smokes* or both are true.

- (49b) $\| [VP_1 \text{ or } VP_2] \|_s = 1$ iff either $\| VP_1 \|_s = 1$ or $\| VP_2 \|_s = 1$ or both

(49c)	VP ₁	VP ₂	$[VP_1 \text{ or } VP_2]$
(49c.i)	1	1	1
(49c.ii)	1	0	1
(49c.iii)	0	1	1
(49c.iv)	0	0	0

This is the way in which such connectives are analyzed in classical (Boolean) logic. Such an analysis has proven extremely fruitful for many purposes. Moreover, there is little doubt that the analysis in question is ultimately rooted in the way in which negation, etc., works in natural language; such an analysis indeed captures at least certain natural uses of the relevant words. What is unclear and much debated is whether such an analysis stands a chance as a full-fledged (or nearly so) analysis of the semantics of the corresponding English words. There are plenty of cases where this seems *prima facie* unlikely. This is

so much so that many people have concluded that while Boolean operators may be distilled out of language via a process of abstraction, they actually reflect normative principles of good reasoning more than the actual semantics of the corresponding natural language constructions. Of the many ways in which this problem might be illustrated, I will choose the debate on the interpretation of *or*.

The interpretation of *or* provided in (49a), (49b), and (49c) is the inclusive one: in case both disjuncts turn out to be true, the disjunction as a whole is considered true. As we saw, this seems adequate for certain uses but not for others. The exclusive *or* can be analyzed along the following lines:

(50) Exclusive <i>or</i>			
	VP ₁	VP ₂	[VP ₁ or VP ₂]
(50.i) 1	1	0	
(50.ii) 1	0	1	
(50.iii) 0	1	1	
(50.iv) 0	0	0	

As the readers can verify by comparing (49a), (49b), and (49c) with (50), the two interpretations of *or* differ only in case (i); if both disjuncts are true, the whole disjunction is true on the inclusive interpretation and false on the exclusive one.

So, the thesis that *or* is ambiguous can be given a precise form. There are two homophonous *ors* in English. One is interpreted as in (48a), (48b), and (48c), the other as in (50). Illocutionary agents choose among these options on pragmatic grounds. They go for the interpretation that is best suited to the context. Determining which one that is will involve knowing things like the topic of the conversation (e.g., are we talking about a single job or more than one), the purpose of the conversational exchange, the intentions of the speaker, etc.

We mentioned that Grice proposed an alternative view, however. We are now in position to spell it out more clearly. If you look closely at the two truth tables in (49a), (49b), and (49c) vs. (50), you'll notice that in all the cases in which the exclusive *or* comes out true (namely case (ii) and case (iii)), the inclusive one does, too, i.e., in our terms, $[p \text{ or}_{\text{exclusive}} q]$ entails $[p \text{ or}_{\text{inclusive}} q]$. The former is, thus, stronger, more informative than the latter in the following precise sense: it rules out more cases. If you get the information that $[p \text{ or}_{\text{exclusive}} q]$ holds, you know that case (ii) or case (iii) may obtain, but case (i) and case (iv) are ruled out. If you know instead that $[p \text{ or}_{\text{inclusive}} q]$ obtains, you know that you might be in case (i), (ii), or (iii); only case (iv) is ruled out. Your degree of uncertainty is higher. So $\text{or}_{\text{exclusive}}$ is more restrictive; $\text{or}_{\text{inclusive}}$ is more general (more liberal we said). Things being so, suppose for a moment that *or* in

English is unambiguously inclusive (i.e., its interpretation is the most general, less restrictive of the two); this does not rule out at all the possibility that we are in case (ii) or case (iii). The exclusive construal, in other words, might arise as a special case of pragmatic strengthening. It is as if we silently add to, say, (51a) something like (51b).

(51a) John or Mary will be hired.

(51b) (... but not both)

The silent addition of (51b) to (51a) might be justified through a reasoning of the following sort:

(52) The speaker said (51a); let us assume she is being cooperative and not hiding on purpose any relevant information. This entails that she has no evidence that both John and Mary have been hired, for otherwise she would have said so. Assuming, moreover, that she is well-informed about the facts, this furthermore entails that she thinks that in fact (51b) holds.

So in this view, the base interpretation (viz. (51a)) is enriched through an inferential process that draws on principles of rational conversational exchanges and on factual knowledge about the context. The relation between (51a) and (51b) can thus be analyzed as a case of implicature (cf. on this, e.g., Horn (1989), Levinson (2000), and references therein).

The debate on how the two interpretations of *or* come about is important and shows different ways in which semantics is taken to interact with broader considerations pertaining to communication. Whether the two interpretations of *or* are a matter of ambiguity or arise as an implicature, I want to point out a generalization concerning their distribution, which I think shows something important concerning how language works. I will argue that the cases in which *or* is construed preferentially inclusively are (1) predictable, and (2) determined by structure. Then, I will put forth a hypothesis as to why this is so.

We have seen that a sentence like (16a), repeated here as (57a), is interpreted as in (57b), namely exclusively:

(53a) If I got it right, either John or Mary will be hired.

(53b) If I got it right, either John or Mary but not both will be hired.

Now take the consequent (i.e., the main clause) in the conditional in (53a) and move it to the antecedent, and the interpretation tends to shift:

(54a) If either John or Mary are hired, we'll celebrate.

(54b) If John or Mary or both are hired, we'll celebrate.

So, moving a disjunction from the consequent to the antecedent seems to have a systematic effect on the interpretation of *or*. The same holds for the pair in (55a) and (55b):

- (55a) Every student will either take an exam or write a paper.
 (55b) Every student who either takes an exam or writes a paper will satisfy the requirements.

In (55a), *or* is within the VP, which corresponds to the second argument of *every*, according to the analysis sketched in the section **Semantic Modeling**. Its preferred interpretation is exclusive. In (55b), *every* is in a relative clause which is part of the subject NP (namely, the first argument of *every* according to the analysis in **Semantic Modeling**). Its preferred interpretation is clearly inclusive.

A further class of contexts that displays a similar effect are negation and negative verbs. Compare (56a) and (56b):

- (56a) I believe that either John or Mary will be hired.
 (56b) I really doubt that either John or Mary will be hired.

Sentence (56a) is likely to get the interpretation ‘I believe that either John or Mary but not both will be hired.’ Sentence (56b), on the other hand does not have a parallel reading. It rather means ‘I really disbelieve that John and Mary stand a chance.’

The list could go on. But these examples should suffice to instill in the reader the idea that there is a systematic effect of structure on the interpretation of *or*. A doubt might linger, though, as to whether it is really in the nature of structure to have this impact. Take, for example, the pair in (55a) and (55b). Is it the position of disjunction that makes a difference? Or is it rather our knowledge of how classes normally work?

This is a legitimate question. Noveck *et al.* (2002) address it experimentally. They designed a reasoning task, in which logically naïve subjects are asked to judge whether a certain inference is sound or not. For example, subjects were asked to judge whether one can infer (57c) from (57a) and (57b):

- (57a) If there is an A, then there is a B or a C.
 (57b) There is an A.
 therefore:
 (57c) There aren’t both a B and a C.

Subjects were told that this was about inferences that could be drawn (on the basis of the given premises) concerning letters written on the back of a certain blackboard. What would your answer be? The experimental subjects overwhelmingly accepted the inference in (57a) and (57b). What is interesting is that in

terms of classical Boolean logic (which takes *or* to be inclusive) this inference is invalid. It is only valid if *or* in (57a) is interpreted exclusively. At the same time, subjects rejected inferences of the following form:

- (58a) If there is an A, then there is a B and a C.
 (58b) There is an A.
 therefore:
 (58c) There is a B or a C.

Again, this seems to make sense only if *or* in (58c) is interpreted exclusively. Things change dramatically if *or* is embedded in the antecedent of a conditional:

- (59a) If there is an A or a B, then there is a C.
 (59b) There is an A; there is also a B.
 therefore:
 (59c) There is a C.

Subjects overwhelmingly accepted this inference as valid. But this is only possible if *or* in (59a) is construed inclusively. Our raw intuition thus finds experimental confirmation, one that passes all due controls (the inferences were mixed with others containing other connectives and quantifiers, so that subjects were not conditioned to devise an answering strategy, and the order of presentation was duly varied, etc.). What is interesting is that these experiments only involved meaningless letters A, B, C... so scripts, contextual clues, knowledge of the world can hardly be imputed any role in the outcome. If there is a systematic effect on the interpretation of *or*, this must be due to the meaning of conditionals, of disjunction, and to the positioning of the latter. Nothing else is at play.

The reader may wonder how one manages to find out which structures affect the interpretation of *or*. The answer is that such structures were familiar from another phenomenon: the licensing of Negative Polarity Items (NPIs). NPIs are lexical items like *any* or *ever* that seem to require the presence of a negative element:

- (60a) * There is any cake left
 (60b) There isn’t any cake left.

NPIs are acceptable in the contexts that favor the inclusive interpretation of *or* over the exclusive one:

- (61a) * If we are in luck, there are any cookies left
 (61b) If there are any cookies left, we are in luck.
 (62a) * Everyone had any cookies left
 (62b) Everyone who had any cookies left shared them.

This correlation is striking, for the two phenomena (the distribution of *any* and of inclusive vs. exclusive *or*) seem to have little in common.

The next question is whether the relevant contexts have some common property. The answer seems to be

positive and, surprisingly, points in the direction of a rather abstract, entailment-based property. Positive contexts typically license inferences that go from sets to supersets. For example, (63a) entails (63b) and not vice versa.

- (63a) There are Marlboros.
- (63b) There are cigarettes.

The set of cigarettes is a superset of the set of Marlboros; so the entailment goes from a set to its supersets. Negation reverses this pattern: (64b) entails (64a) and not vice versa:

- (64a) There aren't any Marlboros.
- (64b) There aren't any cigarettes.

Now the VP portion of a sentence with *every* (i.e., its second argument) patterns with (63a) and (63b):

- (65a) Everyone had Marlboros.
- (65b) Everyone had cigarettes.

Sentence (65a) entails sentence (65b) and not vice versa. So does the consequent of a conditional

- (66a) If you open the drawer, you'll find Marlboros.
- (66b) If you open the drawer, you'll find cigarettes.

But the NP argument of *every* (its first argument) inverts this pattern just like negation, as we saw in the **Semantic Modeling** section:

- (67a) Everyone who had Marlboros shared them.
- (67b) Everyone who had cigarettes shared them.

Here it is (67b) that entails (67a) and not vice versa. The same applies to the antecedent of conditionals:

- (68a) If you smoke Marlboros, you'll be fined.
- (68b) If you smoke cigarettes, you'll be fined.

Sentence (68b) entails (68a); on the other hand (68a) could be true without (68b) necessarily being true (in a town in which Marlboros but no other brand is banned).

In conclusion, the contexts that favor the inclusive interpretation of *or* share a semantic property that has to do with entailment patterns: they all license entailments from sets to their subsets. Such a property has come to be seen as the property of being *downward entailing* (where *down* refers to the directionality of the entailment from sets to smaller ones). If this characterization is correct, this means that speakers to the extent that they interpret *or* as shown, must differentiate such contexts, and hence must be able to compute the entailments associated with the relevant structure.

The next question is why *or* tends to be interpreted inclusively in downward entailing structures. I will only hint at what strikes me as a highly plausible

answer. As we saw above, in plain unembedded contexts, exclusive *or* is stronger (i.e., asymmetrically entails) than inclusive *or*. The set of cases in which exclusive *or* is true is a subset of the set of cases in which the inclusive one is true. We evidently prefer, everything else being equal, to go for the strongest of two available interpretations. Now, negation and, in fact, all downward entailing structures, as we just saw, reverse this pattern. Under negation, first becomes last; i.e., strongest becomes weakest. In the case of disjunction, the negation of inclusive *or* is stronger (i.e., entails) the negation of exclusive *or*. I'll leave it to the readers to persuade themselves that this is so. Now why is this observation relevant? Suppose we go for the strongest of two alternatives (i.e., we maximize informativeness, everything else being equal); for disjunction, in downward-entailing contexts inclusive *or* is the strongest interpretation; in nondownward-entailing contexts exclusive *or* is the strongest. This explains the observed behavior in terms of a rather simple principle that optimizes information content on the basis of the available expressive resources.

So pragmatic strengthening (via a generalized implicature) correlates harmoniously with the entailment properties of various elements.

Conclusions

We have sketched a view of semantic competence as the implicit knowledge a speaker has of how the information content of various expressions is related. We have proposed to classify the hosts of semantic relations in three major families: entailment-based, presupposition-based, and implicature-based. Given two sentences, speakers can judge whether they entail each other or not, whether they presuppose each other or not, and so on; and they can do so with finite cognitive resources. We have sketched a denotational semantics that accounts for such a competence (i.e., provides a model for it). Our semantics takes the form of a calculus in which entailments, presuppositions, and even (certain) implicatures re-emerge as theorems. Such a model is formal in the sense of being explicit (building on the tradition of logic and model theory). It is, however, also substantive, in that it models a human cognitive capacity (i.e., the ability to semantically relate sentences to each other). We have seen two simple applications of this approach, to the analysis of determiners and connectives. We have also discussed a case of pragmatic enrichment. What we found is that the interpretation of *or* as exclusive or inclusive follows a pattern sensitive to downward entailingness (much like what happens with negative polarity items). If this is so, then

entailment patterns are not simply an invention of logicians or linguists. They must be constitutive, in an unconscious form, of the spontaneous knowledge that endows speakers with their linguistic abilities.

Formalism/Formalist Linguistics

P ten Hacken, University of Wales, Swansea, UK

© 2006 Elsevier Ltd. All rights reserved.

In formalist approaches to linguistics, the form of language is described independently of other aspects, such as its function. Mentalist approaches, including Chomskyan linguistics, Lexical-Functional Grammar, and Head-Driven Phrase Structure Grammar, aim to describe and explain the linguistic competence of a speaker. Purely formalist approaches, including Generalized Phrase Structure Grammar and Montague Grammar, study language as an abstract object. In Chomskyan linguistics, a grammar describes the individual speaker's competence, and universal grammar describes the genetically determined language faculty. The language faculty is essential for (first) language acquisition. This model is also used as a basis to explain aspects of language use.

General Characterization

Language can be studied from a variety of perspectives. Formalist approaches to linguistics have in common that they focus on the form of language. This does not mean that other aspects of language – for example, its use – are necessarily ignored. It does

mean, however, that the aim is to describe the form of language independently of these other aspects.

An alternative interpretation of the label formalist for an approach to linguistics is that the aim of such an approach is to express generalizations about language in terms of a formalism. Although this property is logically independent of the focus on form, formalist approaches generally satisfy both interpretations.

The assumption that the form of language is determined by an autonomous system is shared by all formalist approaches. Autonomy implies that the system can be described independently of other systems. It does not imply that there is no interaction with other systems. It is this autonomy that makes it worthwhile to study language through its form.

Two main positions can be identified on the question as to how this autonomous system is realized. One is the mentalist view, which assumes that language is a knowledge component in the mind/brain of the speaker. This is the position adopted, for instance, by Noam Chomsky. The other position is formalist in the narrow sense. It assumes that a language is an abstract object. This view is found especially in the logical tradition of formal semantics and implies that what individual speakers know is an imperfect reflection of the actual language.

Formalist approaches to linguistics are opposed to approaches that focus on the function or use of language. The latter include functionalist linguistics and sociolinguistics. The aim of functionalist linguistics is to explain the form of language through its function. An example of a phenomenon often studied in this way is grammaticalization. Grammaticalization is the process by which content words become function words or morphemes. Sociolinguistics studies the use of language without drawing conclusions about the nature of the underlying formal system. An example of a phenomenon studied in sociolinguistics is politeness. The relationship of these two approaches to formalist ones is not the same. Functionalist linguistics denies the autonomy of the language system, because it tries to explain it on the basis of external factors. Therefore it is not compatible with formalist approaches. Most work in sociolinguistics, however, can be interpreted as complementary to formalist approaches. Often it is neutral as to the choice of a formalist or a functionalist framework.

Among formalist approaches, Chomskyan linguistics occupies a prominent position. It is a long-established research program that attracts significant numbers of scholars. In the nearly 50 years of its existence it has provoked extensive discussion, so detailed documentation exists about its assumptions and their implications. Botha (1989) gave a systematic overview of the issues and summarized the discussion of the 1970s and 1980s. Most alternative formalist approaches to linguistics make a point of specifying how they differ from Chomskyan linguistics. For this reason, this article will first describe the research program of Chomskyan linguistics before describing the main alternative approaches within formalist linguistics. Finally, the position of language use in these approaches will be addressed.

The Research Program of Chomskyan Linguistics

Most formalist approaches to linguistics have the ambition to develop linguistics as an empirical science. In an empirical science, a theory explains the observations in the real world by describing the underlying system. Work in an empirical science is often conceived of as consisting of a cyclical succession of four stages, known as the empirical cycle. According to the empirical cycle, scientific work starts with the collection of data. The next stage is to find generalizations about these data. Then a theory is hypothesized to explain the data. Finally, this theory is tested, which supplies further data, often contradicting the theory under consideration, so that the cycle can start again. Progress in science is

the incorporation of more and more data in the explanatory scope of the theory. This model is still adopted, usually implicitly, by many researchers working in empirical science.

Logically, the empirical cycle is not sufficiently explicit to guide scientific research. At every stage, too many alternative possibilities would have to be considered. In the transition from generalizations to theories, for instance, a sufficiently imaginative researcher could come up with more theories than they could test in their lifetime. In scientific practice, however, such problems do not arise. In the perception of most researchers, it is difficult enough to come up with a single theory that fits the data. The discrepancy between the logical plethora of theories and their scarcity in scientific practice can be explained by assuming a research program. A research program is the set of assumptions guiding the researcher toward sensible decisions at any step in the empirical cycle. These assumptions need not be conscious to the researcher and are often not formulated explicitly. In the same way as a good chess player does not see all logical possible moves but only the sensible ones, a scientist working in a research program automatically constrains the possible theories to be considered.

Chomskyan linguistics is a research program in linguistics. As such, it should be distinguished from Chomsky's linguistic theory. While both were conceived by Noam Chomsky in the late 1950s, their aims and later development are strikingly different. Chomsky's linguistic theory went through a number of stages in its development, including standard theory (ST) in the 1960s, government and binding theory in the 1980s, and the minimalist program in the 1990s. In each of these stages, tree-structure representations of sentences played a role, although the constraints on the production and manipulation of these tree structures varied. Chomskyan linguistics, by contrast, remained stable during this period. It does not refer to tree structures but specifies what a linguistic theory should explain and how such a theory should be evaluated.

Chomskyan linguistics defines the object of study as the knowledge of language a speaker has. This knowledge is called the linguistic competence or internalized language (I-language). It is not open to conscious, direct introspection, but a wide range of its manifestations can be observed and used as data for the study of language.

Competence is opposed to performance. Performance includes various types of language use; for instance, a collection of utterances, a corpus of texts, a set of grammaticality judgments, and a set of results of psycholinguistic experiments. They can be used as data in linguistic research, but in every case

the relationship they have to competence should be kept in mind in their use. Naturalistic data (utterances, texts) reflect the interaction of competence with a number of other factors. Examples of such factors are knowledge of the situation in which the utterance was made, intention on behalf of the speaker, memory limitations, and degree of fatigue. Because the role of many of these factors is poorly understood, it is often difficult to use naturalistic data as evidence for the nature of competence. Experimental data also reflect competence in interaction with other factors, but in setting up the experiment, an attempt is made to control the non-competence factors. The most frequently used type of experiment is the grammaticality judgment. There is no principled reason for treating it in a special way, but because grammaticality judgments are both highly informative and easy to obtain, they have always been widely used in Chomskyan linguistics.

A grammar is a theory about the competence of an individual speaker. It describes the competence as the system underlying the observed data. As such, the grammar explains the data. The term grammar is sometimes also used to refer to competence, but this use is potentially confusing. In early stages of Chomskyan linguistics, including Standard Theory as outlined by Chomsky (1965), grammars were described in terms of rewrite rules and transformations. At this stage of the theory, rewrite rules of the type $S \rightarrow NP VP$ generated tree structures and transformations that operated on these tree structures to account for phenomena such as subject-verb agreement, passive constructions, and question formation.

The research program as described so far encounters a serious epistemological problem. If we assume a set of grammaticality judgments as our data there are infinitely many grammars (sets of rewrite rules and transformations) consistent with our data. This is a result obtained in mathematical linguistics, the theory of formal grammars. Because the aim of linguistics is to identify the grammar describing the actual competence, we need a method to distinguish this grammar from the other ones compatible with our data. Adding more data of the same type will exclude some grammars but not reduce the problem in a principled way. At any point in time, our set of data will be finite, and for any finite set of data there are indefinitely many different grammars.

As a solution to this problem, Chomskyan linguistics adopts a cross-linguistic perspective, focusing on language acquisition. In other theoretical frameworks, different languages have been compared to reconstruct a common parent language (historical-comparative linguistics) or to find universals

(typology). In Chomskyan linguistics it is assumed that certain genetically determined properties of the human mind are necessary for language acquisition. These properties are therefore reflected in one way or another in any language. By comparing different languages, linguists working in the Chomskyan framework try to find evidence of properties of the language faculty that make the acquisition of these languages possible. These properties have little in common with superficial inductive generalizations. Biologically, they are supposed to be encoded genetically in the same way as, for instance, the property that the human hand has four fingers and an opposed thumb, but they are more difficult to detect because individual languages may reflect them in different ways.

Various indications make the choice of language acquisition as the source of universals plausible. Acquisition of a language is necessary for its existence. Data from child language acquisition show that for many features of syntax, the child does not learn by repetition and resists correction. Moreover, the discrepancy between competence and performance leads to many ungrammatical and incomplete sentences in the input that children receive. The resulting I-language acquired by the child, however, is much more similar to the competence of the people in his or her environment than is a grammar that allows the sentences in the performance the child receives as input. While such considerations make a language faculty as a genetic component of the human mind plausible, conclusive empirical evidence for or against such an assumption is hard to imagine and probably impossible in principle.

In the research program of Chomskyan linguistics, the language faculty is described by a universal grammar (UG). Sometimes the language faculty is also called the language acquisition device or UG, but these names are less appropriate, because the former conflates the knowledge incorporated in the language faculty with its use and the latter conflates it with its description. The interaction of UG and grammars of individual I-languages is an essential factor in the epistemological validity of the Chomskyan research program. Since the purpose is to describe on the one hand all I-languages and on the other the language faculty that makes their acquisition possible, a proper balance has to be struck between what is genetically determined and what is acquired. If UG is too restrictive, it will not be possible to come up with grammars for all I-languages. If UG is not restrictive enough, it will not be possible to explain the learnability of the I-languages.

The interaction of the main components of Chomskyan linguistics can be represented as shown

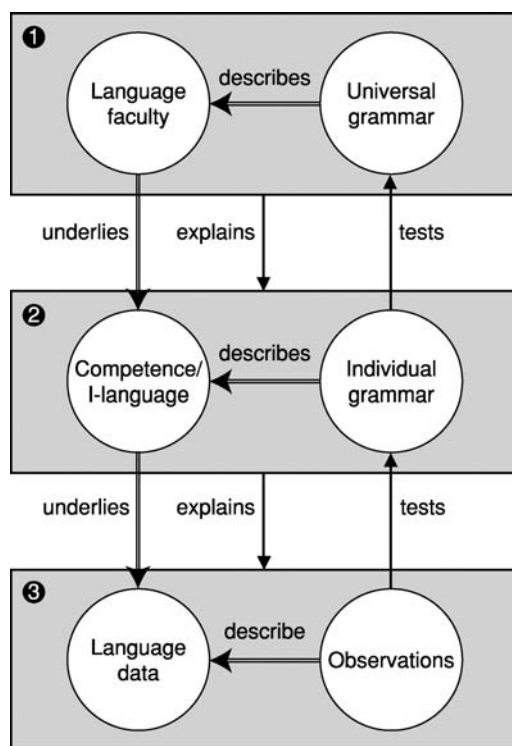

Figure 1 The research program of Chomskyan linguistics.

in **Figure 1**. Language is studied at the universal level (1), at the individual level (2), and at the level of data (3). These levels are represented as the three numbered boxes. On the left we find the real-world entities at each level: the language faculty, the individual competence, and the performance data. On the right we find the constructs of linguistics: UG, individual grammars, and observations about performance. At each level, the linguist's construct describes the real-world entity. In interpreting the relationships between the different levels, it should be kept in mind that there are many instances of the lower level corresponding to a single instance of the higher level. For example, by describing an I-language, a grammar can explain (aspects of) a large set of performance data. Conversely, these data can be used as a test for the grammar. At the higher level, UG describes the language faculty and explains thereby (aspects of) a large set of I-languages. Again, conversely, I-languages can be used as a test for UG, because UG has to allow for a descriptively adequate grammar that is in addition learnable.

While Chomsky (1965) recognized the epistemological need for UG, he also observed that ST did not incorporate the mechanisms for formulating it. By progressive generalization and cross-linguistic comparison, a model of the language faculty emerged, which was formulated as the Government

and Binding Theory (GB theory) by Chomsky (1981). In this model, UG consisted of a number of principles, which were universal. Differences between I-languages were accounted for by including parameters in the principles. A parameter specified a number of options, typically two. In language acquisition, parameters were set by selecting one of these options. The grammar of an I-language was thus determined by the parameter settings selected. The Minimalist Program (MP) outlined by Chomsky (1995) changed many of the theoretical assumptions of GB theory but continued to adhere to the principles and parameters model. An example of a difference between GB theory and the MP is the way movement was constrained. In GB theory, the individual transformation rules of ST were replaced by a single, general rule move α . This meant that anything could move anywhere unless a constraint prohibited it. In the MP, the perspective was reversed: every movement had to be motivated.

A noteworthy consequence of Chomskyan linguistics is that language can be studied at the level of individual I-languages or of the universal language faculty, but not at the level of major languages or dialects. There is no sense of **language** in Chomskyan linguistics, such that, for instance, David Beckham and Paul McCartney share the same language. Since they have different minds, they cannot share a mental component. The similarity of their I-languages, which by no means amounts to identity, can be explained as a consequence of the limited choice permitted by parameter settings, combined with a large overlap in vocabulary.

Other Mentalist Approaches

Adoption of a formalist approach to linguistics and acceptance that language is a knowledge component in the mind of the speaker by no means implies adherence to the research program of Chomskyan linguistics. There are many different ways of elaborating these two basic assumptions into a research program. Although the research program of Chomskyan linguistics has been debated more intensively and developed in more detail, this does not mean that the others are less valid in any sense. In this section, two approaches will be presented that have been developed over the past decades and continue to attract a significant group of researchers: Lexical-Functional Grammar (LFG) and Head-driven Phrase Structure Grammar (HPSG).

Lexical-functional grammar emerged in the late 1970s as a reaction against certain aspects of Chomskyan linguistics. However, the main focus of debate at the time was not the research program

of Chomskyan linguistics, as described in the previous section, but the interpretation of a number of individual theoretical results. An example of a prominent issue was the so-called psychological reality of grammars for individual languages. In any stage of Chomskyan linguistics, a sentence is represented as a tree structure generated by rewrite rules and subsequently affected by transformations that move elements of the tree to other positions. The principles and parameters of GB theory are constraints on rewrite rules and movement. Some researchers argued that if such a grammar is a psychologically real description of the speaker's competence, a sentence that requires more movement operations or more complex ones should take longer to process than one with fewer or simpler movement operations. They devised psycholinguistic tests to evaluate this hypothesis and found that processing times were not affected in the expected way. Cognitive complexity could not be related to the complexity of syntactic derivations in a transparent way. This stimulated the development of grammar formalisms in which the role of transformations was reduced or eliminated. Lexical-functional grammar is one of the most successful of them.

As the contributions to Bresnan (1982) indicated, LFG was devised mainly by Joan Bresnan. Instead of tree structures and transformations, LFG has a tree structure and a functional structure for each sentence. The functional structure represents grammatical functions, such as subject and predicate, in a feature structure. The tree structure and the functional structure are linked by a unification-based procedure. In this way, transformations are no longer required, so the problem they pose for the psychological reality of grammars no longer arises.

At first sight, the research program of LFG was not fundamentally different from that of Chomskyan linguistics. Superficially, the main difference seems to be the nature of the grammar formalisms. A grammar in LFG also intends to describe the competence of a speaker. When we consider the universal level, however, a more principled difference can be observed. Lexical-functional grammar assumes that the formal mapping procedure between the tree structure and the functional structure is universal. This assumption constrains the formulation of grammars in a way parallel to the function of UG in Chomskyan linguistics. This means that the language faculty in LFG is interpreted not as the knowledge needed for language acquisition but as a mechanism for language processing. Therefore, the research program of LFG can also be represented as in **Figure 1**, but rather than UG, a universal mechanism for processing language, i.e., mapping between form and meaning, describes the language faculty.

Another influential framework is HPSG, which emerged in the 1980s. Originally, as represented in Pollard and Sag (1987), it was strongly influenced by logical approaches to syntax (generalized phrase structure grammar; see the following section) and semantics (situation semantics). In more recent representations of the framework, Pollard and Sag (1994) and Sag and Wasow (1999) adopted a mentalist position. However, work in HPSG is more concerned with developing grammars than with discussing their status. In HPSG formalism, tree structures have been replaced entirely by feature structures. Rather than different levels of representation that are related to each other by transformations or other operations, HPSG adopts a single level. All information about what is called a sign (lexical item, phrase, sentence, etc.) is combined into a single structure. This includes phonology, syntax, semantics, and pragmatics. Relationships between components of the structure are indicated by co-indexation. This applies to both, for instance, a pronoun and its syntactic antecedent and to syntactic, semantic, and pragmatic representations of the same item. The grammar formalism in HPSG seems to be understood as a universal mechanism with language-specific parameters for building up feature structures, which suggests a research program similar to the one for LFG. The HPSG literature is in general more interested in describing individual languages than in the nature and status of universals.

Purely Formalist Approaches

Formalist approaches to grammar are often labeled as generative grammar. The term 'generative' stems from the theory of formal languages. A formal grammar is a set of rewrite rules that generates a set of sentences. The set of sentences is called a language.

In early Chomskyan linguistics, the mechanism of rewrite rules played an important role as a theoretical device. The role of the formulation of individual rewrite rules has declined in the transition to the principles and parameters model in GB theory. The conception of a language as a set of sentences goes counter to the definition of the research topic in any stage of Chomskyan linguistics. Chomsky (1986) called it an E-language (*E* for externalized), as opposed to the I-language he wanted to study.

Other linguists and philosophers pursued the idea that natural language should be studied as a set of grammatical sentences. Quine (1972) summarized the epistemological implications of this assumption. In his view, a language like English is ultimately a set of grammatical sentences. Although this set is infinite, it can still be determined for each sentence

whether it is grammatical or not. For any set of sentences, there are infinitely many possible grammars. Rather than finding the correct one among them, this approach considers all of them as equally valid. It is not the knowledge of individual people that is interesting but only the language as an abstract object. English is an abstract object, of which individual speakers have imperfect knowledge, encoded in potentially quite different, more or less imperfect grammars. This position was elaborated by Katz and Postal (1991).

In the domain of semantics, this view of language has a long tradition in the philosophical study of truth and reference. In formal logic, models were developed for calculating whether a particular logical formula is true or false, given a specific assignment of truth values to primitive statements. It was Richard Montague who extended the use of these mechanisms to complex phenomena in natural language, such as quantification. Compared to Chomskyan linguistics, Montague grammar reversed the relative importance of syntax and semantics. Whereas in Chomskyan linguistics, syntax is the central area of linguistics, Montague found syntax not interesting by itself but only as a contribution to calculating the semantics of sentences. He used categorial grammar instead of rewrite rules to represent syntax. In this formalism, constituents are characterized in terms of their relationship to referring expressions and truth values. His model-theoretic semantics was meant to characterize formally the set of possible worlds corresponding to the truth of a sentence. After Montague's death, a large number of followers continued to pursue this idea.

In the domain of syntax, the progressive formulation of principles generalizing over individual rules in Chomskyan linguistics gave rise to the objection that the grammars were no longer generative because they were not formalized in enough detail to determine whether a particular sentence would be generated or not. Many researchers who had been attracted by Chomsky's (1965) ST because of its formality did not accept this development. The introduction of these principles was motivated at least in part by the problems caused by the excessive mathematical power of transformations. Therefore, Gerald Gazdar developed a formalism that approached this problem in an alternative way and dispensed with transformations altogether. In Generalized Phrase Structure Grammar (GPSG), even long-distance dependencies are expressed in terms of a purely 'context-free grammar' (CFG). A CFG consists only of rewrite rules of the type $A \rightarrow \alpha$, where A stands for a single symbol and α for a string of symbols. An example of a long-distance dependency is found in the following: *Who*

did John think Mary loves? Here, *who* is interpreted as the object of *loves*. In Chomskyan linguistics, the usual way of expressing this is to say that *who* originates to the right of *loves* but is moved to the start of the sentence by a sequence of transformations. Gazdar demonstrated that a CFG can account for this as well as for many other relationships traditionally described with transformations. To achieve this, he decomposed syntactic categories into feature structures and formulated so-called meta-rules. A meta-rule is a rule that takes a CFG rule as input and produces another CFG rule. Meta-rules have access to individual features inside the syntactic categories.

One of the main advantages of CFGs is their easy implementation on a computer. However, Barton *et al.* (1987) demonstrated that the system of meta-rules adopted in GPSG made grammars computationally intractable. Although GPSG has lost much of its attraction and is no longer pursued as a major grammar formalism, it contributed significantly to the theory of feature structures and was at the basis of the HPSG formalism.

Formalist approaches in the narrow sense do not have a research program parallel to the ones discussed in earlier sections of this article. They do not investigate language as an empirical entity, represented in the speaker's mind but only as an abstract object. As a consequence, their research is not guided by the empirical cycle. It is more similar to formal logic or mathematics, in which theorems are derived from axioms. The axioms correspond to the grammar and the theorems to the sentences. Contrary to common practice in logic and mathematics, formal linguistics starts with a set of theorems (grammatical sentences) and non-theorems (ungrammatical sentences) and searches for a set of axioms that generates all theorems and none of the non-theorems.

Aspects of Language Use

In all formalist approaches to linguistics, the theory of the language system is intended to be part of a general, empirical account of language-related phenomena. The hypothesis that language can be described as an autonomous system, whether realized as a component of the mind/brain or as an abstract system, implies that the interaction between this system and other factors can be invoked to account for phenomena related to language use.

The use of language in communication is one of the most prominent phenomena that have to be covered in this context. Yet it should be emphasized that language and communication are independent. This contrasts with the view adopted in functionalist

approaches, where communication is invoked to explain language. In formalist approaches, language is not considered as a tool for communication (although it can be used for communication) and communication is not seen as dependent on language (although it often involves language). By recognizing this mutual independence, relevance theory, as developed by Sperber and Wilson (1986), is compatible with formalist approaches to the description of language. In HPSG, the information pertaining to language use can be encoded directly in the feature structures representing signs. In Chomskyan linguistics, it has been suggested that there is a mental component of pragmatic competence interacting with grammatical competence. Kasher (1991) elaborated this idea.

Since the 1980s, a number of other phenomena based on language use have gained a prominent position on the research agenda of Chomskyan linguistics. They include first and second language acquisition and language change. The reason for their prominence is that they can be used as a source of data about the principles and parameters involved in language.

Whereas the logical problem of language acquisition is at the basis of the language faculty hypothesis discussed in the section on Chomskyan linguistics, the practical problem of first language acquisition is analyzed in the principles and parameters model as the process of parameter setting by the child on the basis of performance data provided by people in the child's environment. The main question here is how the language faculty interacts with general cognitive development. Wexler (1999) advocated the hypothesis that the language faculty matures in the process of language acquisition. Lust (1999) proposed instead that the language faculty remains stable and that the first language competence is a distinct component from the language faculty.

Second language acquisition leads to a state of competence that is usually less than the one achieved for the first language. It is often called interlanguage. In Chomskyan linguistics, an interlanguage is an I-language. The question is what roles are played by such factors as the learner's cognitive development, the type of access to the language faculty, and the first language competence in the emergence of interlanguage competence. Gregg (1996) gave an overview of some of the main positions.

Language change is the historical development of languages such as English. In Chomskyan linguistics, English is considered an epiphenomenon. Its change means that different generations of speakers have systematic differences in language competence. Lightfoot (1999) presented a model in which it is assumed that parameter settings determining a

speaker's grammar do not change in their lifetime but their use of the grammar does. The use of certain constructions may drop below a threshold necessary for a new generation of speakers to set the parameters in the same way as their parents. When this happens, the language is perceived as having changed.

In this section, various fields have been touched upon that crucially involve language use. The role that these fields play in approaches to linguistics that assume an autonomous system of language demonstrates that this assumption does not prevent the study of language use. Instead, it guides this study in a fruitful and constructive direction. The principles and parameters model adopted in Chomskyan linguistics stimulates this type of research in particular, because it provides external evidence about the nature of principles and parameters.

Frame Problem

C Viger, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Origins of the Problem

The frame problem, first explicitly identified by John McCarthy and Patrick Hayes (1969), arises in the attempt to design artificially intelligent machines. Intelligent reasoning includes temporal reasoning, such as planning actions or explaining a causal sequence of events. Correct temporal reasoning requires knowing the effects that actions will have in the situations in which they are performed, both the changes and the nonchanges. The frame problem, in its original formulation, is the problem for designers of artificially intelligent systems of how to represent nonchanges, such as when a cup is moved yet its color does not change. For humans such inferences are trivial, just common sense. However, designing systems with common sense has proved to be an extremely difficult problem for artificial intelligence (AI) researchers, making the frame problem of much wider interest than a technical design problem, as it touches on age-old philosophical questions about understanding intelligence – not least as it is manifest in human conversation. In the hands of philosophers, the frame problem has come to refer to a cluster of issues concerning the relevance of the content and speed of human thinking.

McCarthy and Hayes were working within the tradition of using formal logic to design intelligent systems. To handle temporal reasoning, McCarthy had developed the situation calculus, an instance of

first-order predicate logic. The formalism indexes time discretely. It includes rules that allow a system to deduce the results of an action, given a description of some situation, i.e., it can produce a description of the situation that results from the action. They applied the formalism to very simple 'toy worlds,' such as a block world consisting of only a small number of blocks on a table and a few simple actions, such as moving or stacking, that could be performed on the blocks. What McCarthy and Hayes realized was that the rules specifying the explicit effects of some action were not sufficient for the system to completely describe the situation resulting from that action. For example, if in situation S1, block A is on block B, and blocks C and D are on the table, the formalism does not allow the system to deduce that in S2, the situation resulting from moving block C onto block D, block A remains on block B. An additional rule specifying that block A remains on block B when block C is moved is required for that inference. The rules specifying the nonchanges during an action are called frame axioms, because they specify the stable frame of reference in which the action occurs.

Frame Axioms Result in Computational Overload

The difficulty with using frame axioms is not that the correct inferences cannot be drawn; it is, rather, that a very large number of frame axioms are required even in simple worlds. For example, adding a painting action to the block world requires distinct rules specifying that each block remains the same color when any block is moved or stacked or when any other

block is painted. As worlds become more complex, the number of frame axioms comes to overwhelm the system. Most of the system's computations are irrelevant deductions about what has not changed, making the system very slow and thus unable to function in real time. Also, the formalism is very brittle. Most frame axioms will be false in at least some situations when concurrent actions are possible, leading to false conclusions of the sort that humans rarely endorse. Given the complexity of our environment, it is extremely implausible that we reason using frame axioms. Thus, insofar as it is a goal of AI research to help us understand intelligent behavior, the use of frame axioms is unsatisfactory. The problem, then, is how to represent nonchanges without using a large number of frame axioms.

The Sleeping Dog Strategy and Nonmonotonic Logics

A main strategy for solving the frame problem within AI is called the sleeping dog strategy. The idea is 'to let sleeping dogs lie,' which in the context of the frame problem is to make the assumption that things remain just as they are when an action is performed unless there is some explicit indication of a change. This method uses databases containing statements describing situations. When an action is performed, its effects are computed. Statements that cease to hold are deleted, and statements describing changes are added. All other statements correspond to the nonchanges, so they are included in the database for the resulting situation; the nonchanges are stored in memory, rather than computed.

A difficulty for using the sleeping dog strategy as a solution to the frame problem is that there are often exceptional effects of actions. For example, moving a block does not ordinarily change its color, but it does in the exceptional case that the block is moved under a spray painter. Intuitively, what is required to handle exceptional cases is the ability to draw a new conclusion upon learning new information. Formally what is required is that by adding a premise, the deduction of one conclusion can be transformed into the deduction of a different, contradictory conclusion such that the original conclusion no longer follows – on pain of inconsistency. The difficulty is that classical logics do not have this property. They are monotonic, which is to say that any conclusion that follows from a set of premises also follows if further premises are added. In response, AI researchers have developed a number of nonmonotonic logics in which adding new premises blocks the derivation of the original conclusion. Using nonmonotonic logics makes it possible to derive new, contradictory

conclusions when exceptional circumstances formalized as additional premises are added to a derivation. This often involves adding a premise indicating that the action is abnormal in the given situation, so that the usual conclusion ceases to follow.

The Yale Shooting Problem

Even when nonmonotonic logics are used, there are still problems in trying to use the sleeping dog strategy. The most famous such problem is known as the Yale Shooting Problem, introduced by Hanks and McDermott (1986). The scenario in the Yale Shooting Problem is that a gun is loaded at some time t . For a number of discrete time units following t , the action taken is to wait. Then the gun is fired at Fred. The intuitively correct outcome is that in the next time unit, Fred is dead. The formalism predicts this by taking the gun's being loaded as the sleeping dog that persists. Though being alive is a state that usually persists, being shot by a loaded gun is abnormal with respect to being alive, so Fred must be dead. The formalism also predicts that Fred is alive, however, by treating the state of being alive as the sleeping dog. The reasoning in this case is that since Fred is alive, the gun must have become unloaded during the waiting, treating the action of waiting as being abnormal with respect to the gun's being loaded. The formalism cannot determine which sleeping dog, Fred's being alive or the gun's remaining loaded, should be left to rest in the given situation, so it cannot predict whether Fred is alive or dead. The problem comes about because in nonmonotonic logics the addition of a premise – the gun is shot – can undermine support for some conclusion. When more than one conclusion can become unsupported – Fred is alive, the gun is loaded – the formalism has no way to decide which one to keep, leading to contradictory predictions about the new situation. In some cases the conflict is a virtue, because it models our own uncertainty of the outcome, but even when the outcome is obvious to us, the formalism is stymied.

Holism Presents a Problem for the Sleeping Dog Strategy

A more general philosophical concern with the sleeping dog strategy results from the holistic nature of commonsense inferences. In the right situation, virtually anything we know might be relevant for successfully predicting the outcome of an action. A dropped paper clip will fall to the ground, unless it is in a magnet field. My love of pizza could even affect the New York Stock Exchange if I order the last slice of pepperoni ahead of a multibillionaire who then

invests irrationally after lunch. There is no principled way that anyone yet knows of for determining which sleeping dogs need to be woken in a particular situation. (This reading of the frame problem as a problem of accessing relevant information is of interest to linguists and philosophers of language attempting to understand what is said in making an utterance over and above its literal meaning. Research here is being conducted at the interface of pragmatics and semantics.)

AI researchers such as McDermott (1987) and Hayes (1987) criticized the broad philosophical interpretation on the grounds that it is not the real frame problem. Instead, philosophers are focused on problems of relevance and prediction, which are related to, but distinct from, the frame problem. Distinguishing these problems is more than mere pedantry; it stems from a general optimism that progress is possible following a divide-and-conquer strategy that is often successful in science. Clear distinctions also further understanding. Philosophers such as Fodor (1987, 2000) are much more pessimistic, since they see the problem as generalizing. Defining the frame problem so narrowly that it is solvable leaves the much wider problem of relevance untouched. Insofar as it is the aim of AI research to design intelligent machines, progress will be impeded until holistic reasoning can be modeled. For example, abductive reasoning, such as judging which of two hypotheses is simpler, faces the same problem of computational overload that we see in the traditional frame problem, and for the same reason, according to Fodor (2000). Whether or not some hypothesis is simple depends on the theory and background assumptions into which it is embedded. As a result, computing simplicity seems to require computing over an entire theory; yet we make simplicity judgments in real time, leaving us with the problem as to how a computational model can account for abductive inferences.

Concluding Remarks

Since the formulation of the frame problem, attempts to solve it have led to many advancements in logic and computer science that are significant in their own right, much as work on Fermat's last theorem developed mathematics. Though researchers do not agree on just what the problem is or the progress that has been made, most agree that progress on the frame problem is central to the development of cognitive science.

Functionalist Theories of Language

C S Butler, University of Wales, Swansea, UK

© 2006 Elsevier Ltd. All rights reserved.

Functionalism within the Gamut of Linguistic Theories

Functionalist theories of language have most often been contrasted with formalist theories, particularly those developed by Chomsky during the past half century. This comparison is useful and will indeed form the starting point for the discussion in this article. However, like many dichotomies in linguistics, this one conceals a much more complex reality. A more realistic way of looking at things would be to posit a linear sequence of approaches, with strongly formalist theories such as Chomsky's at one end and the more radically functional approaches at the other. Even this, though, is still something of an oversimplification: what we really need is a multidimensional model in which the whole space occupied by linguistic theories is populated by groups of theories that form tighter or looser clusters according to their degree of similarity on a wide range of features. In what follows, we examine a number of features that are characteristic of functionalist theories. Much more detailed discussion of many of these points can be found in Butler (2003a: Chapter 1).

A further complication that should be borne in mind as we survey the range of functionalist approaches is the distinction between European and North American functionalism. Important theories initially developed in Europe include Functional Grammar (FG: Dik, 1997a, 1997b) and Systemic Functional Grammar (SFG: Halliday, 1994; Halliday and Matthiessen, 1999, 2004). In the United States, there are two rather distinct kinds of approach: on the one hand, Role and Reference Grammar (RRG: Van Valin, 2005; Van Valin and LaPolla, 1997) belongs to the rather more formal subgroup of functionalist theories; on the other hand, there is a set of approaches, more radically functionalist in nature, that have developed out of the 'West Coast' functionalism of scholars such as Givón, Haiman, Bybee, Hopper, Thompson, DuBois, Noonan, and Goldberg and that are often included, together with Langacker's cognitive grammar, under the label of 'usage-based' models. It is important to be aware that often, in the writing of American functionalists, the labels 'functionalist' and 'functionalism' are used primarily in relation to this last group of models, often with little reference to European ideas.

The Basic Tenets of Functionalism

The three most basic principles of functionalist approaches are that

- they regard communication as the primary function of language, which shapes the forms languages take
- they attribute great importance to external (cognitive and sociocultural) factors in explaining linguistic phenomena
- they reject the claim that syntax is autonomous from semantics and pragmatics.

The most basic tenet of all, from which all others derive to some degree, is that the primary purpose of language is human communication, and that this fact is crucial in explaining why languages take the form they do. This view contrasts somewhat starkly with that of Chomsky, for whom language is essentially a vehicle for expressing thought, with inter-human communication being just one of the uses to which it can be put, and not to be prioritized over other possible functions. Chomsky (1980: 229–230) defends his position by reference to what he regards as noncommunicative uses of language, such as resolving a problem or engaging in what has been called 'phatic communion' in order simply to oil the social wheels. For the functionalist, many such situations would still be communicative, though what is communicated may be largely social or interpersonal in nature rather than purely representational. Furthermore, even if some types of language use are non-communicative, they are, the functionalist will claim, merely parasitic upon the central communicative use.

If we are to study language as communication, then we will need to take into account the properties both of human communicators and of the situations in which linguistic communication occurs. Indeed, a further important claim of functionalism is that language systems are not self-contained with respect to such factors, and therefore autonomous from them, but rather are shaped by them and so cannot be properly explained except by reference to them. Linguists who make this claim belong to the group that Croft (1995) calls 'integrative functionalists,' and they undoubtedly form the largest and most influential group of functional theorists. The main language-external motivating factors are of two kinds: the biological endowment of human beings, including cognition and the functioning of language processing mechanisms, and the sociocultural contexts in which communication is deeply embedded. We might also expect that a functionalist approach would pay

serious attention to the interaction between these factors and the ways in which languages change over time, although in practice this varies considerably from one model to another.

The question of motivation for linguistic systems is, of course, not a simple one. Much of the formalist criticism of functionalist positions has assumed a rather naïve view of functional motivation, in which some linguistic phenomenon is explicable in terms of a single factor. Functionalists, however, have never seen things this way, but rather accept that there may be competing motivations, pulling in different directions and often leading to compromise solutions.

It is important to note that formalists are not necessarily totally opposed to the claim that language is functionally motivated, although this is something that is not often discussed in the formalist literature. Newmeyer (2003a), for example, claims that even hard-line formalists would accept this claim, and that Chomsky has never denied it. The question, for Newmeyer, is how much functional motivation there is, where it is located in the system, and to what extent it should form part of the research program. In particular, Newmeyer claims that functionalists and practitioners of cognitive linguistics have posited a tighter iconic form–function fit than is justifiable and is skeptical of the concept of competing motivations, on the grounds that anything can be explained away by some combination of such antagonistic forces (Newmeyer, 1998: 137–153, 2003b). The solution, of course, is to demonstrate such competing motivations and their antagonistic effects clearly so that functional ‘explanation’ does not become vacuous, a problem that is discussed in Butler (2003a: 19–25).

The great majority of functionalists also believe that within the nonautonomous linguistic system as a whole, that part of it which deals with the forms of language, and which we may call morphosyntax, is also not autonomous but is intimately bound up with the kinds of meaning that it serves to express, divided by many linguists into the semantic and the pragmatic. In other words, functionalists claim that the morphosyntax of languages is motivated by the meanings that it conveys, although we shall see that the various theories differ with regard to the strength with which they hold this position. Indeed, there are some scholars, such as Prince and Kuno, whom Croft (1995) calls ‘autonomist functionalists’ precisely because they do accept the autonomy hypothesis, but it can be argued that these approaches are peripheral to the mainstream of functionalism (Butler, 2003a: Chapter 1). Most functionalists would accept that there is some degree of (at least apparent) arbitrariness in the morphosyntax of any language, but many would again attempt

to link this to the concept of competing motivations. The functionalist position again contrasts with the formalist one, which maintains that the morphosyntax forms a system that can be described and explained independently of meaning.

Summing up the basic characteristics of functionalist theories, we may say that the core of the functionalist position is that language systems and their components are so inextricably linked with the social, cognitive, and historical contexts of language use, and with the meanings that language is used to convey, that it is futile to attempt to describe and explain them except through reference to such factors.

Further Features

There are a number of further features that, although ultimately derivable from the basic tenets, show considerable variability across functionalist theories:

- The attempt to account for the full range of linguistic phenomena rather than merely a ‘core grammar’
- The use of authentic linguistic productions as data
- Recognition and modeling of the flexibility of language in use
- Attention to discourse as well as to the sentence
- A concern with typological variation in language
- An approach to language acquisition in which the child constructs his or her language from the information available in the linguistic environment, given inherent general cognitive capacities and learning abilities

In the following sections, these points are explored in more detail.

Inclusive Rather Than Core Grammars

A truly functional approach, aiming to understand and account for language as communication, cannot restrict its scope to some kind of core grammar, as with Chomskyan theories, but must, in principle, take on the full complexity of languages and our use of them, provided, of course, that the phenomena under study are systematic.

The Use of Authentic Textual Data

If, as functionalists claim, they are interested in studying language as communication, then it is logical to assume that one of the main sources of data for their descriptions and theorizing will be samples of actual communication, in their contexts of use. In other words, we would expect functionalists to make extensive use of authentic language data in their work, particularly those large bodies of material that have been collected in the form of computer-readable corpora.

Flexibility of Meaning and Structure

If we are truly to study language in its communicative role, we must come to terms with the fact that what we say, and the way we say it, responds flexibly to the demands made by the communicative context. There are various aspects to this flexibility: the context-dependent meaning of words; the fact, clear from corpus linguistics, that a good deal of what we say is made up of reusable ‘chunks’ of language rather than generated or analyzed afresh every time we need to express a particular concept (*see*); the fuzzy nature of linguistic categories, which has been modeled through recourse to the specification of prototypes; the fact that structures in actual communication are often much less rigid than the textbook grammars would allow; the emergence of grammatical categories from the requirements of discourse; and the ‘leaky’ nature of the grammars we write to describe languages (Givón, 1995: 9).

A Discourse Grammar, Not Just a Sentence Grammar

Communication normally involves not just single, isolated sentences but also larger stretches of multi-propositional discourse. It follows that a truly functional theory should reflect this fact by containing not just a sentence grammar but also a model of discourse structure and of how the two interact.

Typological Orientation

Functionalists are interested not only in individual languages but also in ‘language’ as a whole. Since crucial motivating factors such as the human biological endowment and the overall requirements of communication are universal, we may expect that they will be reflected in linguistic universals, although it is also important to realize that because competition among motivations can be resolved in many ways, and because there are considerable differences in the sociocultural conditions under which languages are used, there are also pressures leading to diversity among languages. These concerns are manifested in the interest shown by most functionalists in linguistic typology. As pointed out by Croft (2003: 2), the label functional–typological approach is often given to an approach that seeks to motivate similarities and differences between languages in functional terms rather than in terms of the ‘formal’ explanations sought by Chomskyan linguists. Nevertheless, as Croft (2003: 5–6) also observes, the functionalist and formalist approaches share several fundamental characteristics, although with different emphases: both begin by analyzing language structures (functionalists in terms of function and Chomskians in

terms of formal properties), both are concerned with the central question of what constitutes a possible human language and posit universal constraints, both abstract patterns from the data (the functionalist across languages and the formalist within languages), and both explain universals in terms of universal human abilities (the functional typologist in terms of general cognitive and sociocultural abilities and the formalist in terms of innate principles specific to language).

A Constructivist Account of Acquisition

Functionalist theories, with their communication-in-context view of language, understandably tend to favor a constructivist view of language acquisition, according to which enough information is available in the linguistic environment for the child to be able to construct a grammar, with the help of more general cognitive factors and learning capacities. This is not to say that functionalists totally reject the possibility of innate characteristics: what is at issue is rather the nature of this endowment. For the functionalist, it is more likely that what is innate will be a set of general cognitive principles and predispositions to learn rather than some concrete set of linguistic rules and principles.

Important Functional Theories

This section examines briefly the European and American functionalist approaches mentioned at the beginning of this article, with particular reference to the features of functionalism discussed previously.

Functional Grammar

Functional Grammar was developed by the Dutch linguist Simon Dik and his colleagues from the late 1970s onwards. Dik made a strong commitment to the centrality, in the formulation of a grammar, of the concept of communicative function:

The primary aim of natural languages is the establishment of interhuman communication; other aims are either secondary or derived. (Dik, 1986: 21)

In the functional paradigm, ... a language is in the first place conceptualized as an instrument for social interaction among human beings, used with the intention of establishing communicative relationships. Within this paradigm one attempts to reveal the instrumentality of language with respect to what people do and achieve with it in social interaction. (Dik, 1997a: 3)

Dik (1986) discussed in detail the kinds of external motivation that we need to appeal to in explaining why languages are as they are, also bringing in the concept of competing motivations.

Dik (1997a: 8) also rejects the thesis that syntax is autonomous from semantics and pragmatics:

Semantics is regarded as instrumental with respect to pragmatics, and syntax as instrumental with respect to semantics. In this view there is no room for something like an 'autonomous' syntax. On the contrary, to the extent that a clear division can be made between syntax and semantics at all, syntax is there for people to be able to form complex expressions for conveying complex meanings, and such meanings are there for people to be able to communicate in subtle and differentiated ways.

He does, however, accept that grammar is a structural system, governed by a set of rules and principles, which should nevertheless be explained, wherever possible, in terms of the functioning of language as a communicative device. For example, Dik (1986: 27–28, 43) points out that expression types used to express politeness, deference, and social distance are typically longer and more complex than less polite counterparts, and that this reflects two types of iconic principle: that of diminution vs. augmentation (important = high, big; unimportant = low, small) and the avoidance of directness (see also Haiman, 1983).

The previous quotation suggests that pragmatics, as the driver of semantics, which in turn is the driving force behind the syntax, should play an important part in FG, and Dik does indeed set up a criterion of pragmatic adequacy for his grammar. He also makes a commitment to a criterion of psychological adequacy, according to which the grammar should at least be compatible with what we know of the storage and processing of language. It has been argued, however, that Dik's work failed to live up to both of these standards of adequacy. A number of new models have been put forward under the general umbrella of FG, one of whose aims is to increase the level of pragmatic and (particularly) psychological adequacy. Particularly important among these new developments are the Functional Procedural Grammar (FPG) of Nuyts, the Functional Discourse Grammar (FDG) of Hengeveld, and the Incremental Functional Grammar (IFG) proposed by Mackenzie. Mention should also be made of the Functional Lexematic Model of Mairal Usón and colleagues, which is derived from FG and Coseriu's theory of lexematics. This model pays considerable attention to cognitive aspects of lexical structuring. Brief introductions to all these models can be found in Butler (2003a, 2003b), together with evaluations of the extent to which they, as well as the parent theory of FG, attain the standards of adequacy they aspire to.

FG and its variants are committed to providing an account of the full range of phenomena found in the world's languages rather than of some

restricted core grammar. In Dik's work, most examples used to illustrate the grammar were constructed, but proponents of FG and its variants are beginning to take more seriously the need to work with authentic productions, and the use of computer-assisted corpus analysis is increasing. FG has not been among the theories that have foregrounded the flexibility of language, although there is some work on prototypes.

Dik's early model was purely a sentence grammar, although he did present a programmatic model of discourse structure in his later work (Dik, 1997b: Chapter 18). However, there have always been groups of classicists and anglicists in The Netherlands interested in the textual dimension of FG, and this interest has recently increased, with a proliferation of discourse models beginning in the 1990s. Particularly important in this connection are FDG and IFG, which aim to model discourse as well as the sentence grammar.

From its inception, FG has always had a strongly typological orientation. Dik (1997a: 14) states of FG that it should

be *typologically adequate*, i.e., that it should be capable of providing grammars for languages of any type, while at the same time accounting in a systematic way for the similarities and differences between these languages.

This orientation is very clearly reflected in the work of Dik and other FG linguists, and it persists in recent models such as FDG and IFG.

On language acquisition, Dik (1997a: 7) states the following:

From a functional point of view, ... it is certainly more attractive to study the acquisition of language as it develops in communicative interaction between the maturing child and its environment, and to attribute to genetic factors only those underlying principles which cannot be explained as acquired in this interaction.

However, only a limited amount of work on acquisition has been done so far.

Role and Reference Grammar

RRG makes a strong commitment to the study of language as communication, as shown by the following quotation from an early work in which the initial basis of the theory was developed (Foley & Van Valin, 1984: 7):

The theme underlying the various functional approaches is the belief that language must be studied in relation to its role in human communication. Language is thus viewed as a system of human communication, rather than as an infinite set of structural descriptions of sentences.

The last sentence is clearly intended to contrast the perspective taken in RRG with that of Chomskyan linguistics. With this orientation goes a concern for the functional motivation of the grammar: “RRG takes language to be a system of communicative social action, and accordingly, analyzing the communicative functions of grammatical structures plays a vital role in grammatical description and theory from this perspective” (Van Valin, 1993: 2). In practice, RRG prioritizes cognitive over sociocultural explanation, adopting what Van Valin and LaPolla (1997: 15) refer to as a ‘communication-and-cognition perspective’ and leaving out of account, for now, the ways in which language is used in different social situations (Van Valin and LaPolla, 1997: 3, 15).

The autonomy of syntax is firmly rejected (Van Valin, 1993: 2):

Syntax is not autonomous. In terms of the abstract paradigmatic and syntagmatic relations that define a structural system, RRG is concerned not only with relations of co-occurrence and combination in strictly formal terms but also with semantic and pragmatic co-occurrence and combinatory relations.

In other words, RRG postulates that semantic, pragmatic, and syntactic aspects of language, and their combinations, are all crucial in explaining the observed properties of language. Syntax, however, is only relatively motivated by semantics, pragmatics, and cognitive concerns; that is, syntactic phenomena cannot just be reduced to matters of semantics and pragmatics, and there remains some arbitrariness in the formal system.

RRG aims, in principle, to provide an account of all the grammatical phenomena attested in any language. To date, it has not made extensive use of authentic data. Like FG, it does not prioritize the concept of flexibility in its account of languages. It does, however, make use of the concept of prototype, especially in its use of hierarchies of argument types to predict more and less typical choices in two areas: (1) the ‘macroroles’ of Actor and Undergoer in the clause, which are generalizations over more specific thematic relations, and (2) syntactic relations, which RRG conceptualizes not in terms of the usual functions of Subject and Object but, rather, in terms of the notion of the ‘privileged syntactic argument’ of a construction. Although RRG does offer a detailed account of a number of discourse pragmatic areas, such as information distribution (in terms of topic and focus) and switch reference, it has not developed its own model of discourse structure and is still essentially a sentence grammar.

Like FG, RRG is very much concerned with typological matters: “The theory is greatly concerned with

typological issues. In particular, it seeks to uncover those facets of clause structure which are found in all human languages” (Van Valin, 1993: 4). Indeed, Van Valin says that the theory arose out of the question of what linguistic theory might look like if, rather than being centered on English, it were based on languages such as Dyirbal, Lakhota, or Tagalog.

RRG takes a constructivist line on language acquisition (Van Valin, 1993: 2):

The RRG approach to language acquisition ... rejects the position that grammar is radically arbitrary and hence unlearnable, and maintains that it is relatively motivated (in Saussure’s sense) semantically and pragmatically. Accordingly, there is sufficient information available to the child in the speech to which it is exposed to enable it to construct a grammar, and therefore the kinds of autonomous linguistic structures posited by Chomsky are unnecessary.

There have been a number of studies using RRG as a basis for accounting for observed patterns in the acquisition of morphosyntax in a variety of languages (for a summary, together with a discussion of the relationship between acquisition studies and the linguistic theory, see Butler, 2003b: 402–413).

Systemic Functional Grammar

SFG, as developed by Halliday, has its roots in the work of the British linguist J. R. Firth, with influence also from Hjelmlev, the anthropologist Malinowski, and the Prague School. Halliday makes it clear that his aim is to give an account of linguistic communication, or ‘language in use,’ and that languages are as they are because of the functions they have evolved to serve:

Language has evolved to satisfy human needs; and the way it is organized is functional with respect to these needs – it is not arbitrary. A functional grammar is essentially a ‘natural’ grammar, in the sense that everything in it can be explained, ultimately, by reference to how language is used. (Halliday, 1994: xiii)

Both the general kinds of grammatical pattern that have evolved in language, and the specific manifestations of each kind, bear a natural relation to the meanings they have evolved to express. (Halliday, 1994: xviii)

Note that Halliday takes a very strong stand on functional motivation: in principle, everything in the grammar can be motivated through function – a position that some other functionalists would regard as rather extreme. As might be expected from the antecedents of SFG in the work of Firth and Malinowski, Halliday has always been concerned more with social and cultural motivations than with those related to psychological/cognitive processes: indeed, the social dimension is more strongly developed in SFG than in

any other functional theory. This is particularly apparent in the theory of social context developed by Halliday and colleagues in the 1960s and since developed not only by Halliday but also by Hasan, Martin, and others. SFG distinguishes between dialectal and diatypic (or ‘register’) variation in language, and within the latter between the variables of field (concerned with the nature of the social action), tenor (involving the relationships between interactants in communication), and mode (the medium of communication and its role in the linguistic event). SFG has also developed accounts of genres, seen as ways of getting things done linguistically.

SFG totally rejects the concept of an autonomous syntax. The theory is firmly centered on meaning, with syntactic patterns being seen as one mechanism for realizing meanings, a means to an end. Indeed, Halliday prefers to avoid the term ‘syntax’ altogether in order to distance himself from the view that syntax can be opposed to semantics and pragmatics. Instead, he uses the term ‘lexicogrammar,’ chosen to emphasize the claim that grammar and lexis are not totally different kinds of patterning but are part of the same level, different in degree rather than in kind. Both act, together with intonation, to give shape to the meanings we wish to convey. Furthermore, the division between lexicogrammar and semantics is itself not a clear one: “There is no clear line between semantics and grammar, and a functional grammar is one that is pushed in the direction of the semantics” (Halliday, 1994: xix). SFG has not, historically, given high priority to typological matters, and this is reflected in the fact that the most comprehensive accounts of this theory (Halliday, 1994, 2004; Halliday and Matthiessen, 1999) are centered very firmly on English. However, currently there are signs of greater interest in typological matters (Caffarel *et al.*, 2004). The approach to typology in SFG differs sharply from that in FG and RRG in that the emphasis is on the detailed description of particular languages, followed by generalization where possible, rather than on using data from a wide range of languages in order to formulate the theory in the first place.

SFG takes a strongly constructivist line on language acquisition, and there have been longitudinal studies of three individual English-speaking children (for summaries, discussion, and references, see Butler, 2003b: 413–424).

We should note here the existence of a second version of SFG, developed by Fawcett and colleagues. This model takes Halliday’s work as its starting point but modifies it in a number of important ways, one of which is to propose clearly separate levels of semantics and syntax (Fawcett, 2000). However,

this version still treats the semantics as the underlying driving force at the center of the model, with syntax as one means (together with lexical items and intonation) for the realization of meaning.

West Coast Functionalism

So-called West Coast functional grammar was never a single, unified model but, rather, a fairly loose collection of individual approaches. We cannot, therefore, survey the whole area here but will concentrate on one important exemplar, the work of Givón.

Givón subscribes fully to the central tenets of functionalism discussed previously. He (1995: xv) holds that “language (and grammar) can be neither described nor explained adequately as an autonomous system,” but that in order to understand why language is as it is, we must make reference to “the natural parameters that shape language and grammar: cognition and communication, the brain and language processing, social interaction and culture, change and variation, acquisition and evolution.” It is, however, possible for competing motivations to lead to a situation in which grammar “assumes its own reality” (Givón, 1995: 11). The central part played by semantics, pragmatics, and discourse within Givón’s approach to language is abundantly clear in all his work. Furthermore, relationships between linguistic usage, synchronic variation, and language change are discussed in terms of the grammaticalization of originally lexical elements.

Givón rejects Chomsky’s sanitization of the data for linguistic theory building, through the prioritization of competence over performance. He thus takes an inclusive stance on the range of phenomena for linguistic study, and makes frequent use of attested linguistic data, especially in his studies of the frequency distribution of features in different languages and their varieties. Although Givón does not offer a model of discourse structure as such, his work is very much involved with the relationship between grammar and discourse, and context is a key concept in his work. The flexibility of language is an important theme in Givón’s writing, and the concept of prototype is central.

Givón’s work is strongly typological in nature, striking a balance between what is common across languages and their individual characteristics. He (1995: 17) comments that “[w]hile recognizing cross-language typological diversity, most functionalists remain committed to the existence of language universals, presumably both of meaning/function and grammatical structure.”

Finally, Givón takes an explicitly constructivist position on language acquisition, claiming that what the child initially acquires is not syntax, in the

Chomskyan sense, but rather a more rudimentary communicative system, which only later becomes modified toward syntax. He castigates Chomsky for his rejection of communicative function, general cognitive capacities, and sociocultural effects as important factors in acquisition.

Usage-Based Functionalist–Cognitive Models

The label usage-based is used for a group of models that claim that “the speaker’s linguistic system is fundamentally grounded in ‘usage events’: instances of a speaker’s producing and understanding language” (Kemmer and Barlow, 2000: viii). This label brings together models derived from earlier work in West Coast functionalism with approaches such as Langacker’s cognitive grammar and some variants of construction grammar, such as Goldberg’s model. Here, we concentrate on those approaches that derive from the earlier work of West Coast functionalists.

One important strand of usage-based functional linguistics is Hopper’s Emergent Grammar, which takes a very radically functionalist stand in claiming that “[g]rammar . . . is not the source of understanding and communication, but a by-product of it. Grammar is, in other words, epiphenomenal” (Hopper, 1998: 156). Thus, a grammar is seen not as a unified, relatively stable system but, rather, as “an open-ended collection of forms that are constantly being restructured and resemanticized during actual use” (Hopper, 1998: 159). This model is thus firmly rooted in the communicative functions of language and in the cognitive and social contexts of language use. It also pays great attention to relationships between usage, synchronic variation, and diachronic change, through the study of grammaticalization.

Closely related to emergentism is work by Thompson, Hopper, Bybee, and others, which prioritizes the study of authentic conversational data, and in which the concept of broad syntactic templates is replaced by local, lexically bound schemas or collocations, often formulaic in nature, which are specific to the language concerned. These reusable fragments, often with slots for variable items, are seen as empirically verifiable instantiations of the concept of construction, seen as a pairing of form and meaning/function, which is central to construction grammar models. For instance, Thompson (2002) presents evidence that in conversational English what are traditionally analyzed as complement-taking predicates (e.g., *think* + complement clause) are better seen in terms of the combination of (1) a fragment, often formulaic in nature, with epistemic, evidential, or evaluative function, such as *I think/I don’t think/I thought/I*

didn’t think/I guess/I remember, etc., and (ii) a declarative or interrogative clause that carries the main representational content.

Clearly, these usage-based approaches adopt a very inclusive stance on the range of phenomena that are to be accounted for, since the basic aim is to provide an explanatory treatment of the rich diversity to be found in authentic interaction. These models are very much concerned with the flexible responses of language to the contexts in which it is used: they are rooted in the discourse and the ways in which it conditions the choice of what is said and how it is expressed. Considerable weight is given to the frequency of particular items and combinations in language use, on the grounds that frequency demonstrably affects a range of phenomena, including phonological reduction, constituent structure, and the retaining of irregular or even archaic patterns (Bybee and Hopper, 2001). Typological data are also crucial and are taken to support the paramount importance given to discourse motivations for grammatical structuring. Finally, a clearly constructivist line is taken with respect to language acquisition (Tomasello, 2003).

Conclusions

Functionalism, like other terms for ‘schools’ of linguistics, is a convenient label for a complex, varied set of approaches to linguistic theory and description. We have seen, however, that these approaches are united by rejection of the claim that the linguistic system should be studied independently of the cognitive, sociocultural, and temporal factors that at least partially motivate it and also by rejection of the claim that syntax is autonomous from semantics and pragmatics. Functional models regard language as primarily a means for human communication in context and attempt to explain as much as possible in terms of functional motivations, which may compete to give the appearance of arbitrariness in the system. Many also exhibit a number of derived characteristics, although these are much more variable across models: They are not confined to a core grammar but, rather, attempt to take on board the full range of systematic linguistic phenomena; they often use authentic linguistic productions as part of their database; they attempt to model the flexibility and ‘fuzziness’ of language; they are concerned with discourse as well as the sentence grammar; they study typological variation in language; and they adopt a constructivist approach to the acquisition of language by the child.

Finally, it is important to note that there are important similarities between functional models, as defined

here, and explicitly cognitively oriented approaches such as Cognitive Grammar and the various models of Construction Grammar. This is reflected, for example, in the fact that recent usage-based models embrace both functional and cognitive orientations (see also Horie and Comrie, 2000).

Future Tense and Future Time Reference

Ö Dahl, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

It is tempting to think of time simply as a line extending in both directions from the point at which we happen to be located. However, in constructing a theory of temporal semantics, we have to acknowledge that what is ahead of us – the future – is epistemologically radically different from both what is behind us – the past – and what is taking place at this moment – the present. Future states of affairs cannot be perceived or remembered, although they can be the subject of our hopes, plans, conjectures, and predictions. Philosophers such as Aristotle have claimed that the future has a special nature not only epistemologically but also ontologically: statements about the future do not yet have a determinate truth value. In a possible worlds framework, the ‘branching futures model’ can be seen as an expression of a similar idea: time looks like a tree rather than a line, and at any point in the tree there is only one way back into the past, but many branches lead into the future.

Against this background, it is perhaps not so strange that there tend to be asymmetries in the ways in which temporal reference is structured in languages, and that in particular the grammatical category of tense often blurs into modality and evidentiality in the area of the future. Whether for instance the English auxiliaries *shall* and *will* should be seen as markers of future tense or rather as ordinary modal verbs is a much-debated issue, the importance of which depends on the stand one takes on another, equally contentious, issue: how essential it is to uphold the discreteness of grammatical categories. If it is acknowledged that it is normal for the semantics of grammatical items to combine temporal elements with components of a modal, evidential, or aspectual character, it may become more important to study how the weight of these different factors shift over time, in the process of grammaticalization. From this perspective, it is notable that the diachronic sources of what grammars refer to as future tenses typically have exclusively nontemporal meanings, and the temporal meaning elements tend to grow stronger during the course of grammaticalization (‘temporalization,’ in the term of Fleischman, 1983), as future markers gradually obtain an obligatory status. English is a language that has advanced relatively far along the road towards obligatory marking of future time reference. In this regard, it is instructive to compare

English to a language such as Finnish, in which there is hardly any grammaticalization of future time reference. In English, the sentence *It is cold tomorrow*, with the present tense of the copula *is*, sounds rather strange: it is more natural to say *it will (it’ll) be cold tomorrow* or *it is going to be cold tomorrow*. In Finnish, on the other hand, we may replace the adverb *tänään* ‘today’ in the sentence *Tänään on kylmää* ‘Today is cold’ with *huomenna* ‘tomorrow,’ yielding *Huomenna on kylmää* ‘(lit.) Tomorrow is cold,’ without any further changes in the sentence. Thus, Finnish weather forecasts are typically formulated in the present tense, which is hardly possible in English.

The English examples, however, also illustrate two other important points. First, the obligatoriness of future marking in English is not independent of the epistemological status of the statement. If it concerns an event that is fixed by some kind of schedule, English tends to use the present tense, although the time referred to is in the future, as in *The train leaves at noon*. Second, future marking is an area where we often find competition between two or more grammatical devices. For English, *will* and *be going to* have already been mentioned, but there are in fact several additional ways of referring to the future, such as by the present progressive (*We are leaving at four*) or by a combination of *will* and the progressive (*The shop will be closing in five minutes*), neither of which have a progressive meaning in the examples cited. Other languages are similar: Bybee *et al.* (1994) found at least two futures in 70% of the languages in their sample and at least three in close to 25%. As the word ‘competition’ suggests, the choice between the alternative ways of marking future is usually not reducible to any simple semantic or pragmatic distinction: rather, a number of different factors are at play: thus, *will* and *be going to* differ both semantically and stylistically. In many cases, differences between future-marking devices are attributable to what point they have reached in the grammaticalization process; in others, the differences reflect the original meanings of the diachronic sources of the items in question.

Future-marking devices derive historically from a number of sources. Among the most common are auxiliary constructions expressing obligation (‘must’), e.g., English *shall*; volition/intention (‘want’), e.g., English *will*; and motion (‘go’ and ‘come’), e.g., English *be going to*. However, a future tense may develop out of an earlier nonpast or imperfective as an indirect effect, for example of the expansion of an earlier

progressive – the future uses are what is left of the old category after that expansion (possible examples mentioned by Bybee *et al.* (1994) are Margi, Tigre, Pangasinan, and Kui).

In the development of futures, several things happen. To start with, there is normally an initial change of meaning that may involve both what has been called ‘pragmatic strengthening’ and ‘semantic bleaching.’ Thus, a verb of volition, such as *want*, does not normally imply that the willed action is performed; to interpret something like *She wants to leave* as ‘She will leave,’ the meaning of the volitional verb has to be strengthened. But when extended to cases of ‘pure prediction’ such as *It will rain*, the volitional element has to be bleached altogether. Furthermore, the item gradually comes to be used in contexts where it is communicatively redundant, which leads to it being reduced phonetically (e.g., *is going to* > *is gonna*). Eventually, the grammaticalizing item may fuse with the main verb and become affixed to it. A famous example is the French inflectional future as in *il chantera* ‘he will sing,’ which derives from a construction involving the Latin verb *habere* ‘have’ in an obligative meaning. English *shall/will* have not become inflections, although they are usually cliticized to the preceding word in the reduced form *’ll*.

Being usually more advanced on the grammaticalization path, inflectional futures tend to have a wider range of uses than periphrastic ones. Normally, future-marking devices start out in main clauses, which are bearers of the illocutionary force of an utterance. English is an example of a language in which no future time marking is normally found in some types of subordinate clauses, such as conditionals and temporal clauses – for example, *If it rains, you’ll get wet*, where only the main clause is marked for future time reference. As it turns out, future marking in such clauses tends to be restricted to languages with inflectional futures (Bybee and Dahl, 1989).

It was said above that future states of affairs are the subjects of our hopes, plans, conjectures, and predictions. The latter notions also represent what we can call different epistemological bases for statements about the future, and, as was also mentioned above, the way in which such statements are expressed in a language can depend on which kind of epistemological base it has. A major distinction may be drawn between **intention-based** and **prediction-based** future time reference. Particularly in everyday conversation, a large part of what is said about the future refers to plans and intentions of the participants. I announce what I intend to do, or

ask you what you intend to do. This is clearly different from discussing what the weather will be like tomorrow. A straightforward grammatical opposition based on the distinction between intention-based and prediction-based future time reference is less common than one would perhaps think, in view of the apparent cognitive salience of that distinction. Its importance lies rather in the observation that markers that are originally restricted to intention-based future time reference tend to develop into general future markers, which include prediction-based future time reference as central cases but can in the normal case still be used for intention-based future time reference.

Another major parameter is the temporal distance between the speech act and the future time point in the future. Immediacy is often cited as a condition on the use of certain future-marking devices, such as the English *be going to* or the French *aller* + infinitive construction. At a closer look, it often turns out that immediacy is a contributing factor but hardly the only one, as we shall illustrate below. It does happen, however, that more precise restrictions on temporal distance develop, although this is much less common for the future than for the past. Bybee *et al.* (1994) cite Mwera (1994; original source Harries, 1950) as an example of a language that has three different future auxiliaries, *ci* for reference to the same day (hodiernal future), *cika* for the following day (crastinal future), and *jiya*, which they interpret as a general future.

Typological surveys (Dahl, 1985; Bybee, 1994) have shown approximately equal numbers of inflectional and periphrastically expressed futures. In the sample in Dahl and Velupillai (2005), North America, Australia, central New Guinea, the Caucasus, and South Asia come out as areas where languages with inflectional futures are in a clear majority. Among areas where inflectional futures tend to be absent are Southeast Asia (where most languages are isolating) and northern Europe.

Game-Theoretical Semantics

J Hintikka and G Sandu, University of Helsinki,
Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

The leading ideas of game-theoretical semantics (GTS) can be seen by considering the truth condition of a sentence S of an interpreted first-order language. Now, S is true in an obvious pretheoretical sense iff there exist suitable witness individuals testifying to its truth. Thus, $(\exists x)F[x]$ is true iff there exists an individual b such that $F[b]$, $(\forall x)(\exists y)F[x,y]$ is true iff for each a there exists an individual b such that $F[a,b]$, and so on. As such examples show, one witness individual can depend on others. Hence, the existence of suitable witness individuals for S means the existence of a full array of Skolem functions for S , such as the function f in the sentence $(\exists f)(\forall x)F[x,f(x)]$, which is equivalent to $(\forall x)(\exists y)F[x,y]$. Such arrays of Skolem functions can be seen to codify a winning strategy in a simple game (semantical game) between a ‘verifier’ V and a ‘falsifier’ F . The game $G(S)$ associated with S is played on some domain in which the nonlogical constants of S have been interpreted. $G(S)$ begins with S , but at each move the sentence that the players are considering changes. When a move is made, V chooses disjuncts and values of existential quantifiers, whereas F chooses conjuncts and values of universal quantifiers, proceeding from outside in. For $G(\sim S)$ a game rule tells V and F to exchange roles and continue as for $G(S)$. If a play of $G(S)$ ends with a true negated or unnegated atomic sentence or identity, V wins and F loses; if it ends with a false one, vice versa. S is true iff there exists a winning strategy for V and false iff there exists one for F . GTS amounts to the systematic use of such truth conditions.

Game-theoretical ideas thus enter into GTS as highlighting the role of Skolem functions in logical theory. For this purpose, the whole generality of game theory is usually not needed. For instance, the only failure of perfect information that needs to be considered is a player’s ignorance of earlier moves because only the individuals chosen at such moves can be arguments of Skolem functions.

So far, GTS for quantified sentences merely spells out our ordinary concept of truth. In traditional first-order languages, truth in the sense of GTS coincides with truth according to a Tarski-type definition (assuming the Axiom of Choice). But the GTS treatment can be extended and varied in several ways not available otherwise.

1. By allowing informational independence in the sense of game theory, we obtain a more expressive logic called independence-friendly (IF) logic (cf. Hintikka and Sandu, 1989). The greater expressive power is due to the semantic job of quantifiers as expressing dependence relations between actual variables by means of their formal dependence on one another. In the received first-order logic, only some patterns of such dependence could be formulated because the dependence-indicating scope relation is nested and hence incapable of expressing other dependence patterns. This defect is eliminated in IF logic. The role of Skolem functions in GTS is illustrated by the fact that each IF first-order sentence has a sigma-one-one second-order translation, namely, the sentence that asserts the existence of its Skolem functions. Conversely, each sigma-one-one sentence can be translated into the corresponding IF first-order language.

2. The independence of a quantifier (Q_2y) from another quantifier (Q_1x) within whose syntactical scope it occurs can be expressed by writing it (Q_2y/Q_1x). Often it is convenient to restrict this notation to quantifiers of the form $(\exists y/\forall x)$ and to assume that existential quantifiers are independent of one another, as are universal ones. (This simplification is used in this article.) As this slash notation suggests, the semantics of unextended first-order IF languages is not compositional. The limits of compositional methods in the semantics of IF logics have been investigated intensively (Hodges, 1997), and the impossibility of compositional semantics for IF logic normally interpreted has been shown (Cameron and Hodges, 2001; Sandu and Hintikka, 2001). The strength and naturalness of IF logic thus throws serious doubts on compositionality as a desideratum in semantic

theorizing in general. In any case, many noncompositional languages can be treated semantically by means of GTS.

3. GTS can be extended to natural languages by allowing the substitution of names for entire quantifier phrases, as in Hintikka and Kulas (1983, 1985). Then the meaning of this phrase has to be taken into account by suitable additions to the output sentence. For instance, a game step (amounting to existential instantiation) might take the players from a singular sentence of the form

(1) $X - \text{some } Y \text{ who } Z - W$

to a sentence of the form

(2) $X - b - W, b \text{ is a } Y \text{ and } b \text{ Zs}$

Perhaps the greatest difference between natural language games and formal ones is that in the former the order of the application of game rules can be indicated by means other than scopes (labeled tree structures), for instance by the lexical items in question. This shows the limitations of the notion of scope, as argued in Hintikka (1997). At the very least, the two functions of scope (parentheses) have to be distinguished from one another as indicating the limits of binding (binding scope) and as indicating logical priority (priority scope). This distinction helps, among other things, to solve the problem of donkey sentences.

4. GTS can accommodate any concept, logical or nonlogical, whose meaning can be captured by a rule or rules in a semantical game. Cases in point are anaphoric pronouns, epistemic notions, genitives, *only*, and so on (cf. Hintikka and Sandu, 1991). For instance, the semantics of anaphoric pronouns can be captured by construing them, in effect, as existential quantifiers ranging over the individuals hitherto selected by V and F in a play of a semantical game. This extendability of GTS to nonlogical concepts throws into doubt the possibility of any sharp distinction between logical and nonlogical concepts.

By means of IF logic, several mathematical concepts can be expressed on the first-order level that could not be captured in ordinary first-order logic, including equicardinality, infinity, (topological) continuity, and König's lemma. In general, IF logic extends greatly the scope of what can be done in mathematics on the first-order level (cf. Hintikka, 1996).

5. The notion of informational independence plays an especially important role in epistemic logic, including the logic of questions and answers. Their logic depends essentially on the logical properties of the desideratum of a question. Such a desideratum is of the form K_1S where K_1 means *I know that*.

It expresses the epistemic state that an answer to the question is calculated to bring about. The question ingredient is now of the form $(\exists x/K_1)$ for wh-questions and (\forall/K_1) for propositional questions. All the most important notions related to questions and answers can be defined by means of the slash notation.

6. The law of the excluded middle amounts to the requirement of determinacy in semantical games and, hence, is not always satisfied. Determinacy fails, in fact, in IF logic, where the negation \sim is used but not the contradictory \neg negation. The latter can be introduced by a fiat, but within the GTS framework this can be done only when it occurs sentence-initially. When both negations are present, we obtain a logic whose algebraic structure is that of a Boolean algebra with an operator in Tarski's sense. In that logic, we can define generalizations of such notions as orthogonality and dimension.

7. The failure of *tertium non datur* shows that IF logic is closely related to intuitionistic logic. In a sense, IF logic is in fact more elementary than ordinary first-order logic. For instance, an application of the GTS truth definition to a sentence does not involve infinite closed totalities of individuals even when the domain is infinite. If such totalities are relied on, we can give truth conditions also for sentences in which \neg occurs internally. The resulting logic is as strong as the entire second-order logic (with the standard interpretation), even though it is first-order logic in the sense that all quantifiers range over individuals.

In general, GTS shows that our concept of negation is irreducibly ambiguous between the strong (dual) negation \sim and the contradictory negation \neg . This fact explains a number of features of the behavior of negation in natural language (cf. Hintikka, 2002a).

8. The simplest type of IF sentence that is not translatable into ordinary quantificational notation is of the following form, known as a Henkin quantifier sentence:

(3) $(\forall x) (\forall y) (\exists z/\forall y) (\exists u/\forall x) F[x, y, z, u]$

The negation $\sim S$ of an IF sentence S can be formed in the same way as in ordinary logic. For instance, the negation of (3) is (4)

(4) $(\exists x) (\exists y) (\forall z/\exists y) (\forall u/\exists x) \sim F[x, y, z, u]$

The 'independence-free' meaning of (4) is brought out by its equivalence with (5)

(5) $(\exists f) (\exists g) (\exists x) (\exists y) (\forall z) (\forall u) \\ ((z = f(x) \ \& \ u = g(y)) \supset \sim F[x, y, z, u])$

9. IF logic is misnamed in that it allows for the representation of more dependencies (not just more

independencies) than ordinary logic. A case in point is constituted by irreducibly mutually dependent variables. In order to express them, we have to generalize the notion of function and to take seriously the idea that a functional identity $y = f(x)$ expresses a dependence relation (cf. Hintikka, 2002b). This can be taken to mean that if such an identity fails to have a truth value for some x_o , $f(x_o)$ has to be taken to represent a probability distribution. Such distributions must then be able to be reified so as to act as argument values, too. With this understanding, the mutual dependence of x and y satisfying the condition $F[x, y]$ can be expressed by

$$(6) (\exists f) (\exists g) (\forall x) (\forall y) (x = f(y) \ \& \ y = g(x) \ \& \ F[x, y])$$

which is obviously equivalent to

$$(7) (\forall x) (\forall y) (\exists z/\forall x) (\exists u/\forall y) (x = z \ \& \ y = u \ \& \ F[x, y])$$

10. The GTS approach can be varied in other ways, for instance, by restricting V's strategies to recursive or otherwise constructive ones as discussed in Hintikka (1996). In a different direction, a semantic game can be divided into subgames with specific rules for the transfer of information from one subgame to another one. Such subgames can be used for the interpretation of conditional sentences (cf. Hintikka and Sandu, 1991).

11. The notion of truth is put into a new light by IF logic. Tarski's well-known result shows that truth cannot be defined in an ordinary first-order language L for L itself, even when the syntax of L can be represented in L, for instance by means of Gödel numbering. The reason is that quantifiers ranging over numbers as numbers and quantifiers ranging over numbers as codifying numerical expressions must be informationally independent of one another. This requirement cannot be implemented in the received first-order logic. Because such independencies can be expressed in IF logic, a first-order IF language allows the formulation of a truth predicate for itself. Because Tarski's theorem is thus due to the expressive poverty of traditional logic (rather than its excessive deductive strength, as usually thought), definability problems are no obstacles to the explicit use of the notion of truth also in natural languages (cf. Hintikka, 1996; Sandu, 1998). Because much of the recent philosophical discussion of the notion of truth has in effect been prompted by Tarski's undefinability theorem, most of this discussion has to be reconsidered.

12. GTS, in the sense used here, is characterized by the definition of truth of S as the existence of a winning strategy for V in a semantical game G(S) associated with S. This meaning of GTS has to be distinguished from other uses of games and game theory in logic and linguistics, such as dialogical

games (including questioning games), games of formal proof, games of communication, and so on. There are interesting connections between these different kinds of games. For instance, games of formal proof can be considered as mapping the different courses that a play of a semantical game can take. Again, the strategies of deductive games are closely related to the strategies of the corresponding questioning games when all answers are known *a priori* to be true (i.e., games of pure discovery).

13. Historically, GTS was inspired by Ludwig Wittgenstein's notion of language game. Philosophically, these two share the idea that language-world relations are constituted by certain rule-governed human activities. This implies that intentional relations are dispensable in semantics. In neither kind of game are the moves normally made by speech acts or other language acts. Both games are objective in that their theory depends only on their rules.

In sum, GTS is not merely one branch of formal semantics among others. It is an approach to all semantics, based on the possibility of considering the language-world links as being mediated by games in the abstract sense of the mathematical theory of games.

Generative Grammar

J Rooryck, Leiden University, Leiden,
The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Like many linguistic terms, the phrase 'generative grammar' means different things to different practitioners of linguistics. The term 'grammar' itself can be loosely defined as the set of rules that accurately describe the combination of elements in a language. A properly 'generative' grammar is, roughly speaking, a grammar whose rules generate (i.e., produce) all and only the correct combinations of elements in a language. This definition corresponds to the use of generative grammar as a common noun. However, the term 'generative grammar' gradually received a much broader meaning as a proper noun, referring to the specific research program that is associated with the mentalist approach to language launched and developed by Noam Chomsky. In this article, the basic characteristics of both meanings of generative grammar are sketched, and the relationship between them is elucidated.

The narrower, common noun meaning of the term 'generative grammar' originates in mathematical recursive function theory and is also used in computer science. A generative grammar, then, is one of two types of formal grammars, generative and analytic. Such a formal grammar comprises a set of rules, which in turn define a possibly infinite set of finite strings composed of a set of fixed elements. These elements need not be words of natural language; they may be any kind of symbol.

A classical generative grammar contains four components: (1) a finite set of nonterminal symbols, (2) a start symbol contained in the set of nonterminal symbols, (3) a finite set of terminal symbols, and (4) a finite set of production rules that rewrite a (string containing at least one) nonterminal symbol into a string of terminal and/or nonterminal symbols. Rules

apply in any order and any number of times until all nonterminal symbols are rewritten as strings of terminal symbols. The set of strings with terminal symbols that can be generated this way is called the 'language' generated by the grammar. Generative grammars can be classified into four types conforming to the so-called Chomsky hierarchy. These types differ by an increasingly stricter format for production rules and concomitantly fewer formal languages. In this formal sense, the term 'grammar' is therefore used only by analogy with the term 'grammar' in natural languages.

Take a generative grammar that consists of the set of nonterminal symbols $\{X, Y\}$ with X the start symbol, the set of terminal symbols $\{a, b\}$, and the rules $X \rightarrow aYb$, $Y \rightarrow Xb$, and $Y \rightarrow ba$. The arrow inside the rules carries the instruction 'is rewritten as.' Applying $X \rightarrow aYb$, followed by an application of $Y \rightarrow Xb$ yields the intermediate string $aXbb$. This string still contains a nonterminal symbol. Therefore, it requires reapplication of the rule $X \rightarrow aYb$ (yielding $aaYbbb$) and subsequently the rule $Y \rightarrow ba$ to yield a string that consists solely of terminal symbols, in this case $aababbb$. This grammar also generates other strings (infinitely many, in fact), which together constitute the language of this particular generative grammar.

This formal apparatus provides a powerful tool for analyzing natural language. The set of terminal symbols, then, contains the vocabulary of a natural language, say, English. The set of nonterminal symbols contains word class labels (noun, verb, etc.), as well as larger syntactic units, such as noun phrases and sentences. The largest syntactic unit, the sentence, can be taken as the nonterminal start symbol. The production rules of a descriptively adequate grammar generate the set of sentences that an English speaker would understand as uniquely English, and they fail to generate sentences and phrases that are not judged to be proper English by such a speaker. An English

speaker will readily accept *the red book* as a grammatical unit, but not **the book red*. A more traditional description would then state that in English, adjectives end up in front of nouns and do not appear after them. In a generative grammar of English, this descriptive fact is a result of the order specified in the rewriting rule. In this rule, a noun phrase (NP) is rewritten as a string in which the Determiner (Det) is followed by the adjectival phrase (AP) and the noun (N) in that order: NP → Det AP N. Replacing the nonterminal symbols Det, AP, and N by *the*, *red*, and *book* respectively yields *the red book*. By contrast, the rewriting rule that makes adjectives end up after nouns (NP → Det N AP) is not part of the generative grammar of English. The grammar thus provides a fully explicit syntax of English, rather than the informal or implicit characterization often found in traditional grammars. English speakers have rules that allow them to generate an infinite number of new sentences by using a finite vocabulary, and to interpret entirely new combinations of words. A generative grammar can be recursive: the output of one application of a rewrite rule can serve as the input for a later application of the same rule. This mechanism of recursion is also active in natural language; it is responsible for such sequences as *the sister of the brother of the grandfather of the niece of an acquaintance of my aunt*, which can in principle be infinitely extended by recursion, limited only by performance factors.

Applying this line of thinking in a mentalist context, Noam Chomsky in the late 1950s revolutionized the way of looking at natural language. The study of language could reveal “abstract principles that govern its structure and use, principles that are universal by biological necessity and not mere historical accident, that derive from the mental characteristics of the species” (Chomsky, 1975: 3). The computationally ‘generative’ properties of the grammars of natural languages, and more in particular the property of recursion, is one instance of such abstract, universal, biologically necessary characteristics of the grammars developed by the human species. It should be noted, however, that it is perfectly possible to study properties of formal generative grammars outside of the mentalist context, i.e., generative grammars can be part of nonmentalist approaches to grammar.

Nevertheless, the school of thought on the mentalist nature of language developed by Chomsky and his followers came to be known – rather misleadingly and somewhat erroneously – under the popular name ‘generative grammar’ or ‘generative linguistics,’ this time used as a proper noun. In this much broader meaning, the name should be taken as no more than an expedient, historically motivated *pars pro toto*,

encompassing not only syntax but a mentalist model of grammar also comprising phonology, morphology, and semantics. Accordingly, this school of thought is not limited to finding the generative grammar generating all and only the grammatical sentences of a language in the formal sense defined earlier in this article. Perhaps even more surprisingly, however, the model of generative grammar (as a proper noun) developed in the Minimalist program does not even contain a generative grammar in the common noun sense. Rewriting rules have been entirely dispensed with in favor of more elementary, structure-building operations. Thus, the proper noun meaning of ‘generative grammar’ has entirely outgrown the common noun meaning. Understandably, then, Chomsky himself opposes the use of ‘generative grammar’ to describe his approach to language, preferring terms such as the rather laborious ‘principles and parameters framework’ or the succinctly elegant ‘biolinguistics.’ Despite such opposition, the term is in widespread use as representing the scientific paradigm that has dominated theoretical linguistics for the past 50 years. The remainder of this article is therefore devoted to characterizing generative grammar as a proper noun in the sense already defined.

The approach to language initiated by Chomsky is radically *internalist*. Language is viewed as a species-specific property, part of the mind/brain. The object of study of linguistics as a part of cognitive science is this mental faculty for language. Chomsky radically equates linguistic theory with the study of *I(nternal)-language*, language as an internal cognitive structure. A theory of grammar is a model of the speaker’s linguistic competence, part of the internal structure of his mind. A speaker of a language has internalized a system of rules relating sound to meaning in a particular way. The task of the theoretical linguist is to describe and explain the linguistic competence of a native speaker, the linguistic knowledge of language present in the minds of individuals. A linguist construes hypotheses concerning this internalized system. *E(xternal)-language* is not part of the theory of language and comprises sundry approaches to language as it is used in society, literature, or communication.

The fact that any child can acquire any of the 6000 or so languages in the world in a relatively short period of time and under imperfect input conditions gives rise to the *Immateness Hypothesis*. This hypothesis encapsulates the claim that some set of fundamental characteristics of all human languages must be the same, and part of the *Language Faculty*. The faculty of language is part of the human biological endowment. Children are born with a faculty of language in its Initial State, i.e., the state of

the faculty of language before it is exposed to the input of a particular language. This innate knowledge is sometimes called *Universal Grammar*. Language acquisition requires interaction with the environment, in the same way birds need interaction with the environment to 'learn' how to fly or sing. It is assumed that particular properties of Universal Grammar are parametrized, hence the term Principles and Parameters framework. Particular choices for each parameter of UG lead to specific grammars of individual languages. The Initial State is therefore progressively replaced during acquisition with grammars that come to resemble the Steady State, i.e., the internalized grammar of the language of a given adult speaker.

Generative Semantics

J D McCawley and R A Harris

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition article by James D McCawley, volume 3, pp. 1398–1403, (c) 1994, Elsevier Ltd., with a foreword by Randy Harris.

Foreword (by Randy Harris)

There is little that can or should be added to the definitive epitome of generative semantics you are about to read, by James D. McCawley (1938–1999), except (1) a few words about the importance of McCawley to the movement, which is perhaps, less prominent in an article of his own authorship than it may have been from anyone else's pen, and (2) a few additional citations.

Each of the four main figures McCawley associates with generative semantics – George Lakoff (b. 1941), John Robert (Háj) Ross (b. 1938), Paul Postal (b. 1936), and himself – contributed very substantial elements to its identity, but McCawley embodied the approach, from his feet to his very lively eyebrows, and especially above. He was, in all senses of the phrase, its presiding genius. He helped bring it to life in lengthy, rollicking, mid-1960s telephone calls with Lakoff between Cambridge, Massachusetts, and Chicago. He supplied what many regarded as its strongest arguments and its most compelling analyses, some of which brought Postal into the program. He spent his entire career in the movement's epicenter, the University of Chicago.

He continued to publish comprehensive works in the generative semantics spirit long after the label had fallen into disrepute, especially *Syntactic Phenomena* (1993a) and *Everything That Linguists Have Always Wanted to Know about Logic* (1993b). He believed in generative semantics to the very end, not in all of its specific proposals (relentlessly honest, he cheerfully and publicly dropped analyses that no longer fit his evolving views and cheerfully welcomed views that did, no matter what their origin), and certainly not in the label itself (indeed, he renounced all theoretical labels), but in its substance.

Further reading in generative semantics include Lakoff (1971), McCawley (1976, 1979), Postal (1972), Ross (1972, 1973), Newmeyer (1980, McCawley cites the 1986 second edition; the 1980 first edition has more on generative semantics), Lakoff (1989), Harris (1993a, 1993b), Huck and Goldsmith (1996), and McCawley (1981). Also of note are the two festschrifts for McCawley: Brentari *et al.* (1992) and Zwicky *et al.* (1970/1992).

Generative Semantics (by James D McCawley)

The term 'generative semantics' (GS) is an informal designation for the school of syntactic and semantic research that was prominent from the late 1960s through the mid-1970s and whose best-known practitioners were George Lakoff, James D. McCawley, Paul M. Postal, and John Robert Ross.

GS Positions on Controversial Issues

The name GS gives undue prominence to one of many issues on which GS-ists took positions that conflicted with those of more orthodox generative grammarians, an issue that in hindsight seems arcane because it is intelligible only against the background of the once widely accepted assumption (shared then by GS-ists and their adversaries) that there must be a single level of linguistic structure for which it is appropriate to give a system of 'generative rules' (i.e., rules giving a complete specification of what structures are well-formed on that level) and to which all other levels of structure are related by 'interpretive rules.' The issue commemorated in the name GS was that of whether the privileged level was semantic structure (the GS position) or was a level of syntactic structure as distinct from semantic structure (the position of Chomsky and other 'interpretive semanticists'). The prominence that has been given to that arcane issue should not obscure the fact that GS-ists disagreed with other generative grammarians on many far more substantial issues, such as the following:

- a. Whether sentences were 'grammatical' or 'ungrammatical' in themselves rather than relative to (linguistic and extralinguistic) contexts and to possible interpretations. GS-ists rejected the then popular idea that a language can be identified with a set of sentences and took syntactic derivations as implying that the surface form in question was grammatical not absolutely but only relative to the meaning represented in its deep structure and to any contextual factors to which steps in the derivation are sensitive.
- b. The nature of semantic structure. GS-ists held that semantic structures have the same formal nature as syntactic structures, except for having semantic rather than morphological entities as their ultimate constituents, while interpretive semanticists either were reluctant to make any concrete claims about the nature of semantic structure (e.g., Chomsky, 1972: 137) or adopted a conception of semantic structure that differed considerably in formal nature from syntactic structure (e.g., Jackendoff, 1972).
- c. The nature of syntactic categories. Much work in GS attempted to reduce syntactic category distinctions to distinctions of logical category, supplemented by lexical 'exception features' (e.g., verbs and adjectives would both belong to the category 'predicate,' usually confusingly called 'V' by GS-ists, with adjectives differing from verbs in bearing a feature licensing the application of a transformation that inserts a copula), while other generative

grammarians took syntactic categories to have at most a tangential relation to semantic categories.

- d. The linguistic level or levels relevant to the choice of the lexical material of a sentence. One who holds that there is no level of syntactic deep structure as distinct from semantic structure is forced to recognize syntactic structures whose ultimate units are semantic rather than morphological in nature, such as a syntactic structure [Brutus DO SOMETHING_x (X CAUSE (BECOME (NOT (Caesar ALIVE)))))] underlying *Brutus killed Caesar*. (Here and below, capitalization is used as an informal way of representing semantic units corresponding roughly to the words in question.) GS-ists accordingly proposed transformations that combined semantic units into complexes that could potentially underlie lexical items, e.g., 'predicate-raising' (proposed in McCawley, 1968) adjoined a predicate to the immediately superordinate predicate, thus allowing the derivation of such complexes as NOT-ALIVE, BECOME-NOT-ALIVE (= *die*), BECOME-NOT (= *cease*), and CAUSE-BECOME-NOT-ALIVE or CAUSE-*die* (= *kill*). Intermediate derivational stages involving both lexical and semantic units (such as CAUSE-*die*) needed to be recognized in order to account for, e.g., the parallelism between idiomatic combinations with *come* (*come about*, *around*, *to...*) and their counterparts with *bring*: as Binnick (1971) noted, *bring* corresponded not to CAUSE plus some determinate complex of semantic material but to CAUSE plus *come*, irrespective of whether *come* was used as an independent lexical unit or as part of such combinations as *come about*. Consequently, lexical insertion could not be restricted to a single linguistic level: applications of certain transformations had to be interspersed between lexical insertions. The combinations that could be derived through the application of predicate-raising and other 'prelexical' transformation were supposed to underlie 'possible lexical items.' Since there are infinitely many such combinations but only finitely many actual lexical items in any given language, most correspond to no actual lexical item of the language and were supposed to reflect accidental gaps in the lexicon of the language.

Lexical decomposition analyses were criticized in such works as Fodor (1970), where it was argued that the simple and complex surface forms that supposedly corresponded to the same deep structure (e.g., *Brutus killed Caesar* and *Brutus caused Caesar to die*) did not in fact have the same meanings. It was noted subsequently (McCawley, 1978) that such

discrepancies in interpretation can be explained by a version of Grice's (1967/1989) maxim of manner according to which a simple surface form is preferred to a more complex alternative except when the referent is a peripheral instance of the category defined by the given semantic structure, e.g., using indirect means to cause someone to die would be a peripheral instance of the category defined by 'cause to cease to be alive' and thus would not be in the part of that category where *kill* would preempt the use of *cause to die*. (Syntactic analyses involving lexical decomposition also figured prominently in Gruber, 1965, a work that early GS-ists found congenial despite some important differences between its framework and theirs.)

GS Policies on the Conduct of Research

Of equal importance to these points of theory in their influence on the directions that GS research took and the reception that GS work received were several policies about the conduct of linguistic research, of which the following deserve mention here:

- a. A lack of concern about the compartmentalization of the parts of a linguistic analysis or of a linguistic theory, as contrasted with the concern among Chomskyan generative grammarians with the drawing of boundaries among, e.g., syntax, semantics, and pragmatics. One important facet of this lack of concern was an egalitarian position regarding the different kinds of data that had a bearing on a linguistic analysis: whereas most generative grammarians held that syntactic analyses needed to be supported by arguments in which only syntactic facts figured, GS-ists held that facts about truth conditions, possible denotations, etc., were as relevant as any other kind of facts to evaluating analyses that purported to specify how meanings corresponded to surface forms in the given language, and that supposed syntactic facts were usually at least partly semantic in nature, in that what a speaker of a language judges acceptable is not a sentence in itself but that sentence relative to an assumed understanding of it. Another facet of this policy was GS-ists' insistence that all parts of a linguistic analysis were subject to the same standards of explicitness, simplicity, and factual accuracy, irrespective of how one might wish to demarcate syntax and semantics; by contrast, interpretive semantics has come only gradually and often grudgingly to subject the semantic parts of analyses to the same standards of appraisal as the syntactic parts.
- b. Rejection of the dogma of generative grammar that a fixed notational system is essential to a linguistic theory and that precision can be achieved only by formulating one's analyses in the privileged notational system.
- c. Adoption of a 'static' conception of linguistic rules: rules were thought of not in terms of the popular metaphor of assembling linguistic structures and converting structures on one level into corresponding structures on another, but as 'derivational constraints,' that is, as specifications of what a structure may or may not contain and of how a structure on one level may not contain and of how a structure on one level may or must differ from the corresponding structure on another level. This difference in the conception of rules resulted in difference with regard to what theoretical notions posed 'conceptual problems' (Laudan, 1976) for each approach; thus GS-ists readily accepted rules that specified relations among nonadjacent levels of structure (what Lakoff, 1970b dubbed 'global rules'), a notion that was unproblematic from their conceptual vantage point but outlandish from the vantage point of the 'operation' metaphor for rules, while rejecting the idea of ordering among rules, a notion that was unproblematic for those who accepted the 'operation' metaphor but was difficult to make coherent with the GS conception of rules as derivational constraints.
- d. Disdain for those concerns of Chomskyan generative grammarians that had little connection with linguistic facts or with detailed linguistic description, such as mathematical models and speculation about the extent to which linguistic structure is biologically determined. While GS-ists were receptive to the idea that linguistic structure is profoundly influenced by neuroanatomy, they demanded (e.g., Lakoff, 1974: 171) that claims to that effect be backed up with solid linguistic and solid biology rather than with what they dismissed as arguments from ignorance (i.e., hasty leaps from one's failure to see how some characteristic of languages could be learned to the conclusion that it must be innate).
- e. Eagerness to put in practice in their professional lives many of the ideas of the 1960s counterculture, such as policies of antiauthoritarianism, antielitism, and demystification of science and scholarship, and a belief that one's work should be pleasurable. One of many facets of the GS ethos that these policies helped to shape is what Newmeyer (1986: 133) has disparaged as 'data-fetishism': joy in the unearthing of novel and intriguing facts for which one is not yet in a position to provide a satisfactory analysis; GS-ists, by contrast,

regarded Chomskyan generative grammarians as 'scientific Calvinists' (McCawley, 1980: 918).

Prominent and Influential Analyses Proposed within the GS Approach

Kuhn (1970) notes that one major component of the paradigm of a scientific community is a set of 'exemplars': prestigious solutions to problems, presented to neophytes in the field as paragons of good science, and serving as models for solutions to new problems. (For discussion of the history of generative grammarians' analyses of English auxiliary verbs in terms of Kuhnian notions such as 'paradigm' and 'exemplar,' see McCawley, 1985.) The exemplars for the GS community included a number of analyses that bore an intimate relation to central tenets of GS, for example, lexical decomposition analyses such as were discussed in, First section of this article, and analyses of quantified expressions as being external to their host sentences in deep structure (e.g., *John has read many books* = *many books* + *John has read x*) and as being moved into their surface positions by a transformation of Quantifier-Lowering (QL). (The term QL was in fact applied indiscriminately to a variety of transformations that differed according to the specific deep structure that was assumed; proposals differed with regard to whether just a quantifier or a whole quantified expression was external to the host S, what filled the deep structure position into which the quantified expression was to be moved, and where the quantifier or quantified expression was in relation to the host S.) The best-known arguments given for a QL analysis consisted in demonstrations that the many syntactic rules that were problematic when applied to structures that contained quantified elements became unproblematic if the deep structure position of a quantified expression was external to its host sentence and consequently (in virtue of the principle of the cycle) the rule had as its domain of application a structure that does not contain the quantified expression; for example, this view of the interaction between QL and the transformation of 'Reflexivization' explained why such pairs of sentences as *Every philosopher admires himself* and *Every philosopher admires every philosopher* differed in meaning in the way in which they did, and why reflexivization was applicable only in the derivation of the former. A thorough survey of arguments for a QL analysis is given in McCawley (1988: Ch. 18).

Several other GS exemplars were in fact as consistent with the substantive claims of interpretivist transformational grammar as with those of GS, but were embraced by GS-ists and rejected by interpretive semanticists as much because of policies on

the conduct of research (see previous section) as because of any points of linguistic theory, or simply because of the historical quirk that a particular idea occurred to a member of the one camp before it occurred to any of his counterparts in the other camp. One such exemplar is the analysis of English auxiliary verbs as being verbs that take nonfinite sentential complements in the manner of such verbs as *seem* (Ross, 1969; McCawley, 1971), which Pullum and Wilson (1977) subsequently argued for from within an interpretive semantic framework. (A similar treatment of auxiliary verbs is found in Jespersen, 1937: 92). A second was the proposal (McCawley, 1970, subsequently disavowed by the author) that English had underlying verb-subject-object (SVO) word order, a hypothesis that is, if anything, harder to reconcile with the assumptions of GS than with those of interpretive semantics in view of the dubious nature of the assumption that the order of elements is significant in semantic structure; by contrast, there is no general policy in interpretive semantic versions of generative grammar against discrepancies between deep and surface constituent order, and indeed languages with surface VSO word order are commonly analyzed by interpretive semanticists as having deep VSO word order. Another such exemplar is the 'performative analysis' (Ross, 1970), in which sentences are assigned underlying structures in which a 'hyper-sentence' (Sadock, 1969, 1974) specifies the illocutionary force of the sentence, e.g., *Birds fly* would have an underlying structure of the form [*I tell you [birds fly]*].

The History of GS

The term 'generative semantics' first appears in Lakoff (1963/1976), a work that antedates the development of the Katz-Postal-*Aspects* approach to syntax and prefigures some of Lakoff's subsequent GS work. GS originated in attempts by Postal and Lakoff to exploit novel possibilities that were opened up by the revisions of the transformational syntactic framework proposed in Katz and Postal (1964) and Chomsky (1965) and to fill gaps in the evolving framework. For example, Lakoff's Ph.D. thesis (Lakoff, 1965/1970) originated as an attempt to develop a precise and coherent account of the way in which a lexical item could affect the applicability of transformations to structures containing the given item, and thereby to put on a solid footing those analyses in Chomsky (1965) in which the choice of lexical items affected the possibilities for derivations. In the course of providing such a theory of 'rule model theory.) Coincidentally, the radical revisions that interpretive semanticists were making in their

versions of generative syntactic theory included the adoption of the 'X-bar' conception of syntactic categories, which identified two of the factors that affect the syntactic behavior of a linguistic unit, namely, the difference between a word unit and a phrasal unit, and the part of speech of the unit or of its head. Once a descriptive framework was available that allowed linguistic generalizations to be stated in terms of those factors, considerable progress was made in the analysis of the many syntactic phenomena in which those factors play a role.

No important tenets of GS rule out the adoption of a conception of syntactic categories as defined by these factors *in addition to* logical categories, and indeed a conception of syntactic categories as reducible to those and other factors (with logical category being merely one of several factors that influence a unit's syntactic behavior) is adopted in McCawley, 1977/1982 and subsequent works. However, in the 1960s and early 1970s, an assumption shared by GS-ists and interpretive semanticists impeded GS-ists from adopting such a conception of categories, namely the assumption that syntactic categories must remain constant throughout derivations: a word (with a determinate part of speech) that replaced a complex of semantic material (thus, a unit not having a part of speech) could not differ in category from the replaced unit and thus parts of speech could not be part of the category system. (The widespread misconception that GS analyses allowed linguistic units to change category in the course of derivations in their analysis of, for example, nominalizations overlooks the fact that, according to GS-ists' assumptions, verbs and their nominalizations belonged to the same category. Anyway, analyses of any kind in which the verb *invent* is a constituent of the noun *invention* are not committed to any assumption that the former changes its category in the derivation of the latter: it is whatever it is, regardless of what it is contained in.) Since interpretive semanticists did not require that deep structures match semantic structures (and indeed took delight in arguing that they did not match), there was no obstacle to their having the same categories in deep as in surface structures while drawing the full range of category distinctions provided for by X-bar syntax. The interpretive semantic research program was thus able to become 'progressive' in the sense of Lakatos (1978) because of something extraneous to the issues that were the loci of the substantive disputes between GS and interpretive semantics.

Generic Reference

G Carlson, University of Rochester, Rochester, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Forms of Generic Reference

Generic reference is the term commonly used to describe noun-phrase reference in sentences that express generalizations. Some common examples are found in (1)–(3):

- (1) *Potatoes* are native to South America.
- (2) *The lion* is a fearsome beast.
- (3) *A pencil* is used for writing.

Generic reference is usually understood as making reference to kinds of things (*see also Natural Kind Terms*). When we speak of 'kinds,' we intend a classification system that is based on the denotations of nominal expressions, or sortals, of the language (for one view, *see Gupta, 1980*).

It is now commonly accepted that reference is not only limited to individuals or pluralities of individuals, but also to kinds or types of things as well. This is most evident in noun phrases of the type "this kind of animal," which evidences an overt postdeterminer of the class of 'kind,' 'type,' 'sort,' 'species,' and so on.

- (4) *This kind of animal* hibernates in the winter.

These kind-referring phrases can appear in quantified contexts as well. The analysis then is that the quantifier ranges over kinds of things, just as it ranges over individuals in the more usual instances.

- (5) *Three kinds of swallows* are found in the northeastern United States.
- (6) *Every type of tree* exchanges carbon dioxide for oxygen.

When the postdeterminer element is removed, there remains the possibility of interpreting the noun phrase as referring to or quantifying over kinds. This normally results in a type/token ambiguity. For instance, in (7) one could be talking about individual flowers in a given context or kinds of flowers; similarly for (8). This reading is called a *taxonomic reading* in Krifka *et al.* (1995).

- (7) Sharon photographed *every flower*.
- (8) *Several penguins* inhabit this frozen wilderness.

Examples such as (7) and (8) are ambiguous between a 'kind' reading and the more common individual reading. On the taxonomic reading, the denotation of the head noun is partitioned into subkinds, though this is done contextually since there are multiple ways to naturally partition any domain. For instance, automobiles can be partitioned according to body style (sedan, sports car, station wagon, etc.) or by manufacturer (BMW, Mazda, Volvo, etc.), among other ways. It is commonly noted that if one takes a mass term and syntactically treats it as a count term, by pluralizing it or pairing it with a determiner that selects for singular count nouns only, a taxonomic reading may emerge. Thus, in (9) we are speaking of kinds of wine, and in (10) of kinds of metal:

- (9) *Three wines* are stored in the cellar.
- (10) *Every metal* conducts electricity to some degree.

Another means by which kinds are referred to in natural language is by definite singular noun phrases. In English, this has a stylistically technical tone, but this is not a general feature of other languages. Three possible examples are:

- (11) *The computer* has changed society in many ways.
- (12) Scientists have now documented the entire life cycle of *the three-toed sloth*.
- (13) *The self-cleaning plow* was invented by John Deere.

These exemplify the definite generic on the most natural readings of the noun phrases in these examples. This reading appears in addition to the much

more frequent individual-denoting use of the definite article, and often results in ambiguity. Generally unambiguous is the use of the definite article with only an adjective (e.g., "*The rich* are often oppressors of *the poor*"). Other types of definite kind reference include uses of the proximal and distal demonstratives (*this*, *that*) in the plural. The demonstrative is not, on one interpretation, an actual indexical; instead, it colloquially conveys an emotional attitude toward the kind (Bowdle and Ward, 1995). It appears to be the same use of the demonstrative as when it accompanies a proper name (e.g., "*That Roberto* has done it again").

- (14) *Those spotted owls* (i.e., the kind spotted owl) are constantly being talked about by environmentalists.
- (15) Who invented *these computers*, anyway?

In addition, there are noun phrases that employ adjectives like 'typical,' 'average,' or 'normal,' which have a kind-reference reading, as in "*Your typical businessperson* takes eight plane trips per year." Supplementing definite generics are the consciously introduced Latinate natural kind names, lacking a definite article, which always have an elevated scientific tone no matter the language. This includes examples like '*felis domesticus*' (cat) or '*acer saccharum*' (sugar maple tree). These are unambiguous and always denote kinds. Though not of consciously Latinate origin, the use of 'man' in English as a generic functions in much the same way.

Beyond these are additional means of kind reference in natural language. Bare plurals – that is, plural noun phrases lacking a determiner or quantifier element, at least on one reading – may refer to kinds. The following are three examples:

- (16) *Airplanes* have made intercontinental travel a common event.
- (17) *Lions* once ranged from the tip of Africa to eastern Siberia.
- (18) *Hunting dogs* are most closely related to wolves.

Functioning much the same as bare plurals are undetermined mass expressions (in French, the definite article must be employed), which allow for generic reference to unindividuated domains.

- (19) *Water* is a liquid. (cf. Fr. "*L'eau est un liquide.*")
- (20) *Hydrogen* is the most common element in the universe.

Finally, the singular indefinite article allows for a generic usage, as in the following:

- (21) *A triangle* has three sides.
- (22) *A potato* contains vitamin C.

The bare plural and the indefinite singular are commonly distinguished from the definite singular in English in that the former two usually allow for additional descriptive material in the form of modification, whereas the noun phrases in the definite generic instance are much more limited.

- (23) *A cake without baking powder/Cakes without baking powder/??The cake without baking powder fails to rise properly in the oven.*

Unlike the bare plurals or indefinite singulars, the definite singular is basically limited to expression of well-established kinds, those taken to be already familiar from one's background knowledge. Furthermore, as Vendler (1971) notes, it does not appear they can be 'too general.' Thus, alongside 'the parabola' and 'the circle,' one does not find generic reference to 'the curve.' Currently, a full account of these facts is lacking.

Cross-linguistically, generic reference is carried out by noun phrases with definite and indefinite articles and with determinerless expressions quite generally. In languages without articles, the determinerless form typically has a generic interpretation in at least some sentence positions. While in English the plural form of the definite has generic reference only marginally at best, in German, which is closely related to English, the plural definite may take generic reference quite easily (Delfitto, 1998). If there are languages with articles or other determiners specific to generic reference, they have yet to be brought to general attention, or they may not exist at all.

It is important to distinguish generic reference from the type of sentence in which the expression appears. While generic reference takes place most commonly within the context of a generic or habitual sentence, not all generic or habitual sentences have a noun phrase with generic reference, and generic reference may take place within sentences that are episodic or that make reference to specific events. The clearest examples of this are sentences with the definite singular generic exhibiting the *avant-garde* reading (Krifka *et al.*, 1995). Consider the following example:

- (24) *The horse arrived in the New World around 1500.*

This means that some horses were introduced about that time, but implies that the event was the first time any modern horses had been in that area. To observe a shipment of horses arriving in the western hemisphere in 1980 and use (24) modified by "in 1980" to describe that event would be inappropriate. Other instances where there is kind-reference in episodic sentences, on at least one reading, include the following three examples:

- (25) Today, Professor James lectured to us on the history of *dinosaurs*.
 (26) Marconi invented *the radio*.
 (27) *Monkeys* evolved from *lemurs*.

Theory of Generic Reference

While most semanticists agree that at least certain noun phrases refer to (or quantify over) kinds of things, there is a tradition in which apparent kind reference is treated in terms of quantification over individuals. Stebbings (1930), for instance, suggests that the sentence "The whale is a mammal" expresses a universal proposition (similar to "All whales are mammals"), as does "Frenchmen are Europeans." Russell comments that the sentence "Trespassers will be prosecuted" "means merely that, if one trespasses, he will be prosecuted" (1959: 102), which reduces the analysis of the apparent kind reference (*trespassers*) to an indefinite in a conditional. However, Moore (1944), in response to Russell's theory of descriptions, cites examples like "The triangle is a figure to which Euclid devoted a great deal of attention" and "The lion is the king of beasts," both of which convincingly resist implicit quantificational or conditional analyses.

The most convincing evidence for kind reference in the semantics stems from predicate positions that select for something other than individuals and pluralities of individuals and that readily accept the types of noun phrases reviewed earlier. These are called kind-level predicates. Examples (26) and (27) contain kind-level predicates. While an individual might invent something, the direct object must express a kind of thing and not a particular individual or set of individuals. The verb 'evolve' relates species and other levels of biological classes to other such classes, but not individuals to individuals. The following are other examples of kind-level predicates:

- (28) Dogs are *common/widespread/rare*.
 (29) Insects are *numerous*.
 (30) The elm is *a type/kind of tree*.
 (31) The gorilla is *indigenous to Africa*.
 (32) The Chevrolet Impala *comes in 19 different colors*.

Kind-level predicates are relatively infrequent in any language. Most predicates fall into the classes of either individual level or stage level. Roughly speaking, stage-level predicates speak of highly temporary events and states, such as running across a lawn, eating a sandwich, or being asleep. Individual-level predicates, on

the other hand, speak of more permanent states of affairs, such as knowing French, liking the opera, or being intelligent. Typically, the predicates of a habitual or generic sentence (“x cooks wonderfully”) are individual level. These are discussed in more detail in Carlson (1980), Kratzer (1995), Fernald (2000), and by others. Both stage-level and individual-level predicates select for noun phrases that denote individuals and pluralities of individuals. However, kind-denoting expressions appear with these predicates naturally as well. With both stage-level and individual-level predicates, a quantificational analysis of kind-denoting phrases (quantifying over individuals of that kind) becomes easily possible.

The kind-level predicates do not typically allow for the use of the indefinite singular. An example like (33) is generally deemed not very acceptable:

- (33) ?A lion is a species of animal. (cf. *the lion, lions*)

A continuing controversy centers on the analysis of the English bare plural construction, which has an unlimited distribution in comparison to bare plurals in other languages with articles, such as Spanish or Italian (e.g., Laca, 1990). English bare plurals appear to have different interpretations in different contexts. With individual-level predicates, they have a general interpretation, one that is quantificationally similar to ‘all’ or ‘most.’

- (34) Cats (roughly, all or most cats) sleep a lot.

- (35) Hammers (roughly, all or most hammers) are used for driving nails.

On the other hand, bare plurals also have an existential interpretation in other contexts that is similar to “some” in force.

- (36) *Priceless works of art* (i.e., some works) were delivered to the museum yesterday.

- (37) The rioters threw *stones* through *shop windows*, shattering them.

The primary question is whether in these instances, as well, the bare plural construction is kind-denoting, as most believe it is with kind-level predicates. Carlson (1980) and Chierchia (1998) argue that such a unified analysis is not only possible but also desirable, and both present analyses showing how it can be accomplished. However, others argue that more adequate insight can be gained through an analysis that differentiates true instances of kind reference from those instances where bare plurals appear with individual-level and stage-level predicates and that a quantification over individuals approach is better taken (see Wilkinson, 1991; Diesing, 1992; Krifka *et al.*, 1995).

Grammatical Meaning

Ö Dahl, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Grammatical meaning is usually seen as opposed to lexical meaning. Grammatical meaning thus ought to include any aspect of linguistic meaning that is due to the grammatical structure of an expression rather than to the choice of lexical items. The variation in the definitions found in the literature suggest, however, that the notion is not wholly well understood. Consider, for illustration, the following sample formulations: ‘the part of meaning that varies from one inflectional form to another’; ‘the meaning of a word that depends on its role in a sentence’; ‘the meaning of an inflectional morpheme or of some other syntactic device, as word order.’

A suitable point of departure for a discussion of the notion of grammatical meaning is the classic treatment by Edward Sapir (1921, Chapter V). Although the term ‘grammatical meaning’ itself is not used there, the topic, denoted in the chapter heading as ‘grammatical concepts,’ is the same. According to Sapir’s initial taxonomy, concepts used in language are either ‘concrete’ or ‘relational.’ This coincides, more or less, with the lexical:grammatical distinction. The use of the terms ‘concrete’ and ‘relational’ is thus somewhat different from what is usual. Sapir actually never gives an explicit definition of the terms but comments on his example ‘The farmer killed the duckling’ as follows: “A rough and ready analysis discloses here the presence of three distinct and fundamental concepts” (p. 82) – these are expressed by the three lexical words *farmer*, *killed*, and *duckling* – “that are brought into connection with each other in a number of ways.”

Apparently, then, the relational concepts, which are in this particular case, definiteness of reference, singularity, declarative modality, and ‘subjectivity’ and ‘objectivity’ (meaning the roles as subject and object), and which are expressed through grammatical morphemes or word order, are responsible for the connections between the concrete elements.

However, it is really only the last two, which correspond to the syntactic functions of the two nouns in the sentence, that are relational in the sense of specifying relations between the lexical elements. It is more difficult to understand why, for instance, singularity, ‘expressed by lack of plural suffix -s . . . and by suffix -s in the following verb’ has to be regarded as relational. Moreover, as Sapir notes, the cardinality of referents would not be systematically indicated in many languages, and can be expressed also by lexical means, e.g., by a numeral. The necessary conclusions are that not all relational (i.e., grammatical) concepts are equally essential in language. Sapir is thus led to postulate a category of ‘concrete relational concepts,’ which can vary from language to language, not only in their expression, but also as to their concreteness. Relational concepts such as subjectivity and objectivity on the other hand are not subject to this variation: “The fundamental syntactic relations must be unambiguously expressed” (p. 94). It does seem that Sapir gets a bit entangled in his own reasoning here. On the one hand, he no is longer able to use the distinction between concrete and relational as an explanation for what is grammatical and what is lexical in languages; rather, he takes the grammatical status of a concept as an indicator of its concreteness or relationality, thus opening himself to allegations of circularity. On the other hand, the unequivocally relational concepts, which have to be expressed in languages, no longer display themselves as clearly semantic: he himself speaks of ‘fundamental syntactic relations.’ Sapir’s predicament does reflect the complexity of what Crystal (1997: 107) aptly calls “an area of study that falls uneasily between semantics and grammar.”

Much of the uneasiness is related to the fact that distinguishing the contributions of grammar and lexicon to meaning is no less problematic than separating the roles of genes and environment in an individual. A neat division between grammatical and lexical meaning presupposes that linguistic expressions are like buildings where the building blocks (the lexical items) are independent of the cement

(the grammar). But there is always a restricted number of ways in which a lexical item can be combined with others, and the meaning of the lexical item can often be expressed only in terms of what the resulting combination means. For instance, it is rather difficult to explain the meaning of a verb such as 'borrow' without placing it in a construction such as 'NP borrows NP from NP,' or to explain the meaning of 'father' without mentioning the persons involved in the 'x is the father of y' relation. In formal semantic frameworks such as Montague Grammar, the meanings of relational terms such as 'borrow' and 'father' are specified in terms of functions (in the mathematical sense of 'mapping') from the meanings of the argument expressions to the meaning of the whole. By abstracting away from the content of the specific lexical items, we may arrive at more general constructions, such as 'NP Verb NP Prep NP,' which, in formal semantic terms, have to be interpreted as second-order functions (that is, functions that take other functions as their arguments). It is at the level of constructions that the interface between grammar and meaning has to be sought, as has been argued by proponents of Construction Grammar, and the grammatical meaning of linguistic elements in general can only be understood in terms of their roles in larger constructions.

Grammatical markers and features such as word order and prosody undoubtedly serve the function of making it easier to grasp the structure of a complex expression, in particular the hierarchical relationships between elements. However, the choice

of grammatical elements such as inflectional morphemes may also depend on factors that have little to do with the structure of a sentence and sometimes directly reflect extralinguistic features of the situation or of referents of the discourse. This makes it difficult to uphold a thesis that the meaning of inflectional markers (and of grammatical morphemes in general) is different in kind from that of lexical morphemes.

Rather, inflectional markers differ from lexical morphemes in the role their meanings play in the speech act. A past tense marker in a language such as English normally does not have the function of informing the listener that the event or state referred to took place in the past; rather, it is an obligatory feature (except in some specific styles or genres) of any verb that refers to a state-of-affairs in the past. A related property of inflectional markers is that it is typically difficult or impossible to focus on them or, what can be seen as a special case of focusing, to negate them separately.

Holism, Semantic and Epistemic

R Vallée, Université de Moncton, Shippagan, Canada

According to Epistemic Holism, one does not test hypotheses – individual sentences – one at a time; rather the process of testing hypotheses confronts the whole of science with reality. According to Semantic Holism, the meaning of words and sentences in a language depends on the meaning of each and every word/sentence in that language. The former is widely accepted, whereas the latter is very controversial. Both forms of holism are tied together by the idea that the meaning of sentences is given by their truth conditions.

Epistemic Holism

Scientific theories confront reality via hypotheses, and *prima facie*, hypotheses are tested one at a time. Carl Gustav Hempel (1905–1997) and Willard van Orman Quine (1908–2000) contended that this view was an oversimplification and argued for what is now known as the Duhem/Quine thesis or Epistemic Holism (EH): “Science faces the tribunal of experience not sentence by sentence but as a corporate body: the whole of science” (Quine, 1986: 620).

Science is not compartmentalized. For example, observations made by telescopes are backed by astronomy, physics, optics, and the mathematical theories used in all these theories. The argument behind EH is simple. Assume a logical empiricist’s theory of meaning according to which the meaning of a sentence is given by its confirmation or verification conditions. Consider now any theoretical sentence. Such a sentence cannot be reduced to one single sentence concerning experience and connecting it directly to the world. So, it has no confirmation conditions as a single, independent item. It is connected to reality through a net of sentences, some of which get their truth conditions straight from facts with no regard for other sentences, the so-called observation sentences. It follows that a hypothesis is just a sensor of

the whole science, which confronts reality and is affected as a whole through the hypothesis. Hempel (1950) wrote:

“In order to understand ‘the meaning’ of a hypothesis within an empiricist language, we have to know not merely what observation sentences it entails alone or in conjunction with subsidiary hypothesis, but also what other, non observational, empirical sentences are entailed by it, and for what other hypotheses the given one would be confirmatory or disconfirmatory. In other words, the cognitive meaning of a statement in an empirical language is reflected in the totality of its logical relationships to all other statements in that language, and not to the observation sentences alone.”

In that conception, there is no clear-cut distinction between changing the theory and changing the meaning of sentences. When a hypothesis is proven false, one can alter either other parts of the theory, the so-called auxiliary hypothesis, or the meaning of the sentences of the theory. EH is sometimes offered as a reason for Semantic Holism: EH and the empiricist theory of meaning lead to SH. If the meaning of a sentence is determined by its verification conditions and if they are holistic, the meaning of a sentence is also determined holistically. EH and Semantic Holism are independent views on different topics: scientific theories and language. However, they dovetail.

Semantic Holism

Although EH is sentence oriented, Semantic Holism (SH) covers both sentential and subsentential items. There are different versions of SH, but its basic tenet is that the meaning of a sentence/word is determined by, depends on, or is constituted by, its relation to *all* the sentences/words in a language.

The Argument from Compositionality and the Context Principle

SH is usually not advocated in and of itself. EH can motivate it. It can also be introduced as a consequence of two independently motivated, nonepistemic

linguistic principles and a truth-based semantics. It is based on two principles:

1. *Principle of Compositionality*: The meaning of a sentence is a function of the meaning of its constituents and their syntactic relationship
2. *Context Principle*: “Only in the context of a sentence does a word have meaning” (Frege, 1978: x).

To give the meaning of a word, one must give the meaning of all sentences in which it occurs; that is, the truth conditions of all these sentences. Davidson (1967: 22) followed the argument to its obvious conclusion that “only in the context of a language does a sentence (and therefore a word) have meaning.” The meaning of a word or a sentence is determined by the language to which it belongs.

SH opposes ‘Semantic Atomism,’ which holds that the meaning of a sentence/word is *independent* from the meaning of *all* the other sentences/words in a language. Semantic Atomism proposes either the referent of a word or an abstract entity, like a Fregean sense, as the meaning of a word. From then on, meanings can be piled up.

SH also opposes ‘*Semantic Molecularism*,’ which holds that the meaning of a sentence/word is determined by, depends on, or is constituted by its relation to *some* of the sentences/words in a language.

Both the Principle of Compositionality (PC) and Context Principle (CP) are *a priori*, methodological principles in theoretical semantics. Semantic Holism *per se* is not methodological in nature. Following from two *a priori* principles, it is also *a priori*. It emphasizes that the words/sentences would have no meaning outside that whole and would have a different meaning in a different whole. The PC mentions syntax and applies to complex expressions. SH applies to both simple and complex, structured expressions as well. It is also very general and is not tied to a specific notion of meaning, view on human language, or program in semantics. It simply requires sentences and truth conditions, as opposed to words and referents, to be basic in semantics. SH is also a metaphysical view on language and meaning (see Fodor and Lepore, 1992). In that respect, it has no clear purchase value in theoretical or applied linguistics. On the other hand, as long as it is not incompatible with empirical research, there is no point in rejecting (or in accepting) it.

One can argue for SH in Conceptual Role Semantics (Block, 1986). That conception of semantics is grounded on the functionalist theory of the mind, which takes thought contents to be functionally defined and the meaning of sentences/words to reflect thought contents (see *Mentalese*).

According to Conceptual Role Semantics, the meaning of a token of a linguistic expression is constituted by its inferential properties.

In this view, SH does not follow from methodological principles, but is a plain assertion about meaning. It also concerns tokens, not types, and in that respect, it is an individualistic doctrine. This version of SH is arguably a metaphysical approach to meaning. It is also designed to fit a functionalist view of mental states. Block, the main proponent of Conceptual Role Semantic (CRS), was careful to mention that CRS is not a theory, but a framework for developing semantic theories.

Problems with Semantic Holism

SH raises vexing philosophical issues. Does SH reflect substantial properties of meaning? Does it have an ontological scope? If human languages are holistic, is being holistic an essential property of human languages? Or does SH just echo our way of capturing meaning in a theory, being an artifact produced by our way of theorizing/knowing the semantics of natural languages? SH has *prima facie* implausible consequences for linguistics.

Learning Problem If SH is true, then one cannot learn the meaning of a lexical item without learning a whole language. It also implies that, to understand the meaning of one single word/sentence a speaker utters, one must be able to understand all words/sentences that speaker can utter. To master the meaning of one single word, one must master a whole language. That makes learning and understanding a language an ‘all or nothing’ affair, and it implies that learning/mastering part of a language does not make sense. Friends of holism reply that “in so far as we take the ‘organic’ nature of language seriously, we cannot accurately describe the first steps toward its conquest as learning part of a language; rather, it is a matter of partly learning” (Davidson, 1965: 7). Some (Dressner, 2002) have argued that this fits what we know about the psychology of language learning. Holism apparently opposes the PC – the meaning of one sentence cannot be determined in the way described by the PC because the whole language is involved. However, it is arguable that there is no problem in that quarter. The PC presupposes that the meaning of an unstructured item is determined, and a functional relation is applied to these items. Being determined by and being a function of are two different relationships. Insofar as determination is concerned, *prima facie*, both holism and the PC can be true.

Instability Problem SH also implies that, by adding terms to the language or by altering the meaning of one single word/sentence in a language, one alters the meaning of all words/sentences in that language. As a consequence, the language of a speaker changes constantly because words/sentences are introduced and/or the meaning of lexical items is altered. In addition, two speakers do not speak the same language or use expressions having the same meaning, because the meaning of the words/sentences of a speaker differs from the meaning of the words/sentences of another speaker insofar as they do not share the same vocabulary or produce the same sentences.

Disagreement Problem If two tokens of the same type differ in meaning, then speakers cannot disagree or agree, for that matter, on a sentence. The fact that you accept and that I reject 'Snow is white' does not show that we disagree on anything; the fact that we both accept the same sentence does not show that we agree on anything. The reason is the same in both cases: The tokens have different meaning in the two idiolects, and agreement or disagreement requires sameness of meaning.

SH can be escaped if truth and sentences are not treated as basic in semantic. It can also be avoided if the PC or the CP is rejected. The PC draws wide agreement. The CP is more controversial, and Atomism rejects it. SH inherits certain indeterminacy from the premises leading to it. What do 'is determined by,' 'depends on,' 'is constituted by,' and 'meaning' mean exactly in SH? These terms are not designed to be read in a mathematical way, and they remain controversial. How can sound, *a priori* methodological principles have dramatic metaphysical consequences? Those questions do not make the problem disappear, but prove how opaque it is. The Conceptual Role Semantic version of Semantic Holism can be rejected by refusing CRS.

Semantic Holism and the Philosophy of Mind

Meaning is connected to thought content. Replace the relevant words in the above principles, and you end up with the idea that thought contents have a compositional aspect and that a single thought content is determined by all of one's thought contents. Changing one belief also implies altering the web of beliefs, and hence each belief – this is the instability problem raising its head in the philosophy of mind – and to know one single thought content of a speaker, one

must know all of his other thought contents. Fodor and Lepore (1992) drew attention to the fact that, if SH is true and if meaning is echoed in thought contents, then we cannot share a thought unless we share all of our thought contents, and trying to state psychological laws is a futile project, doomed from the start.

Conclusion

Wherever one looks, one finds only implausible consequences of SH. As a consequence, it never served as the basis for a detailed research program in semantics. However, it did bring the analytic philosopher one step closer to the Hermeneutic tradition. Hermeneutics is thoroughly holistic.

Ideational Theories of Meaning

E J Lowe, University of Durham, Durham, UK

© 2006 Elsevier Ltd. All rights reserved.

Ideational theories of meaning are commonly attributed to 17th- and 18th-century empiricist philosophers such as Thomas Hobbes, John Locke, George Berkeley, and David Hume, and received severe criticism from 20th-century philosophers of language, notably Gottlob Frege and Ludwig Wittgenstein. Unfortunately, the work of the earlier philosophers was seriously misunderstood by their later critics, and much of the criticism was misdirected. In fact, it is highly debatable whether the empiricist philosophers in question were offering theories of *meaning* in anything like the sense that the phrase ‘theory of meaning’ would now be understood (see Hacking, 1975, chapter 5).

Locke devoted an entire book (Book III, ‘Of Words’) of his greatest work, *An Essay Concerning Human Understanding* (Locke, 1975) to the topic of language, focusing on the communicative function of language, the advantages of language, and the abuses of language. According to Locke, the main purpose of language is to serve as a medium for the communication of thought from one thinker to another. Locke, like many of his contemporaries, favored an ideational view of thought – that is, he believed that thinking is essentially an exercise of the faculty of imagination and that thoughts consist in sequences of *ideas* in the minds of thinkers. *Idea* was a term of art in early modern philosophy, as ubiquitous then as the term *concept* is in present-day philosophical writing and playing a partly similar role, to denote a component or ingredient of the contents of thoughts. However, the empiricist philosophers used it equally to denote a component or ingredient of the contents of *sensory experiences*, reflecting the tight connection they presumed to obtain between thought and perception. Locke famously claimed that words “in their primary or immediate signification stand for nothing but the ideas in the mind of him that uses them” (Locke, 1975: 405) – one of the most misunderstood claims in the history of philosophy. Modern readers of

Locke are apt to interpret him as claiming that the *meaning* of a word is an idea in the mind of the speaker, which suggests that he adopted a thoroughly subjectivist – indeed, almost solipsistic – theory of meaning. But such an interpretation mistakenly conflates *signification*, as Locke uses this term, with *meaning* in the semantic sense. Locke is not claiming that words *refer to* or *denote* ideas in the mind of the speaker, but simply that speakers primarily use words to *express* the contents of their own thoughts, for the purpose of communicating those thoughts to others. Locke could happily concede that ‘dog’ in my mouth refers to *dogs*, not to my *idea* of a dog. His point is merely that when I assert, for example, ‘Dogs bark,’ I am expressing a thought that I have concerning dogs – a thought which is about dogs by virtue of containing as one of its ingredients my *idea* of a dog.

To clarify this matter, it is useful to distinguish between three quite different kinds of relations: *semantic* relations, *cognitive* relations, and *expressive* relations (see Lowe, 1995: 145 and Figure 1).

Semantic relations are *word-to-world* relations, such as the reference relation between the word ‘dog’ and dogs. Cognitive relations are *thought-to-world* relations, such as the intentional relation between my idea of a dog and dogs, by virtue of which the former is ‘about’ the latter, or has the latter as its ‘intentional object.’ Expressive relations are *word-to-thought* relations, such as the signification relation (in Locke’s sense) between the word ‘dog’ as used by me and my idea of a dog. In these terms, modern critics of Locke and like-minded early-modern empiricist philosophers may be accused of misconstruing their account of linguistic signification as a theory of semantic relations, when in fact it is a theory of expressive relations. Locke’s primary interest lies not in semantics but in the nature of thought and its relation to language, that is, in cognition and expression. Of course, given an account of word-to-thought (expressive) relations and an account of thought-to-world (cognitive) relations, it is possible to construct an account of word-to-world (semantic) relations, although it seems that Locke himself was not much interested in doing this in any detail. Such

Figure 1 Locke's dog-legged semantic theory.

an account of word-to-world relations will be, in Simon Blackburn's vivid phrase, a 'dog-legged' semantic theory (Blackburn, 1984: 40), because it takes such relations to be the product of two other kinds of relations, cognitive and expressive. There may be problems with semantic theories of this type, but they will only be obscured by misunderstanding the Lockean theory of linguistic signification as *itself* being a theory of semantic, as opposed to expressive, relations. In saying that words are *signs* of ideas in the minds of speakers, Locke means that they are *indicators* of those ideas, which speakers can exploit to enable an audience to gain knowledge of what they are thinking (see Ott, 2004). Locke presumes that signification of this kind is artificial – the product of human invention – rather than natural, but that it is otherwise comparable to the indicator relation between dark clouds and impending rain, the former constituting evidence for the latter.

To evaluate the Lockean approach to language, we need to probe a little more deeply into his account of thought and ideas. Locke divides ideas into *simple* ideas of sensation and reflection, and *complex* ideas that are compounded by the mind out of those simple ideas. By 'reflection' Locke means what would now be called 'introspection.' Examples of simple ideas of sensation would be our ideas of colors, taste, and sounds, while examples of simple ideas of reflection would be our ideas of basic mental activities, such as thinking, desiring, and willing. According to Locke, many of our complex ideas are acquired by the mental process of *abstraction*, or what we might now call 'selective attention,' when we notice that certain types of simple ideas regularly accompany each other in our experience. For example, our complex idea of an *apple* will include various simple ideas of shape, size, color, and taste which we find that we regularly experience in conjunction with one another. It is a matter for dispute among Locke scholars whether or

not he conceived of sensory ideas as mental *images*, and the textual evidence is far from conclusive (see Lowe, 1995: 35–47). It is much clearer that Berkeley, writing a little later, held an imagistic view of ideas and, perhaps wrongly, construed Locke as holding one too. Berkeley famously criticized Locke's theory of abstraction as being incoherent, but the cogency of the criticism seems to depend upon the interpretation of Locke's view of ideas as being imagistic. (Berkeley urged that Lockean abstract ideas must lack determinacy of content in a way that seems problematic only on the assumption that such ideas are, or are relevantly like, images: see Lowe, 1995: 158–161.) Setting aside the controversy over whether or not Locke was an imagist, the essential features of his ideational conception of thought reduce to the following. First, Locke is clearly committed to a strong version of the doctrine that thought is independent of language. Indeed, his central aim in discussing language is to show how easily language can lead us astray if we fail to notice the differences between it and thought. Second, he clearly believes that thinking, involving as he takes it an exercise of the faculty of imagination, is intimately related to and, with respect to its content, ultimately wholly indebted to *perceptual experience*, both sensory and introspective.

Modern critics of ideationism are not only apt to misconstrue the ideational account of linguistic signification as being a semantic, as opposed to an expressive, theory, but also to oversimplify the object of their criticism. For instance, it is sometimes lampooned as maintaining that *every* word in a speaker's mouth signifies a discrete idea in the speaker's mind, including words such as 'not' and 'but,' which Locke himself classifies as 'particles' and to which he devotes a chapter in the *Essay*. It is easy enough to poke fun at the suggestion that 'not' signifies an idea of 'notness,' in the way that 'red' supposedly signifies an idea of redness. But Locke himself suggested nothing so

preposterous, contending instead that negative particles are used to convey a speaker's mental act or attitude of *denial* with respect to a certain thought-content (Locke, 1975: 471). Berkeley's version of ideationism was still more sophisticated, recognizing many uses of language other than simply to express the speaker's ideas – for example, to invoke an emotive response in an audience – and allowed, too, that often we think 'in words' rather than exclusively 'in ideas' (see Olscamp, 1970: 130–153).

Undoubtedly, the disfavor into which ideationism fell during the 20th century was largely due to the conviction that it rendered linguistic meaning excessively subjective. Frege's attack on it was integral to his more general onslaught on psychologism, which he saw as a dire threat to the objectivity of logic and mathematics. This is why he is at pains to distinguish sharply between 'ideas,' which he regards as purely subjective psychological entities, and 'senses' of expressions, which he regards as mind-independent and intersubjectively graspable abstract objects (see Frege, 1960). Wittgenstein is equally antagonistic toward ideationism, which is a prime target of his famous 'private language argument' (see Wittgenstein, 1958: 94–96). Here again the complaint is that ideas are unsuited by their irredeemably subjective and private character to be recruited for a workable account of intersubjective linguistic meaning and communication, and that ideationism unavoidably degenerates into some form of scepticism or relativism.

To the extent that criticisms focusing on the privacy of ideas construe ideationism as postulating ideas as the *meanings* of words, they are misplaced for the reasons explained above. Even so, it is fair to ask of the ideationist how words can serve to *communicate* ideas, given the privacy of the latter – a privacy that Locke himself acknowledged and emphasized. Indeed, for Locke, it is precisely *because* ideas are private – 'invisible, and hidden from others' – that language, in the form of 'external sensible signs,' is needed to 'lay them before the view of others' (Locke, 1975: 405). One might suppose it to be a fatal difficulty for ideationism that no one has direct access to the ideas of another speaker and so is never in a position to tell whether or not the idea that he or she associates with a given word resembles the idea that is associated with it in the mind of someone else. However, Locke himself was fully cognizant of this seeming difficulty and was not at all disconcerted by it. It was he, indeed, who first drew attention to the notorious puzzle now known as the 'inverted spectrum' problem – the question of how I can tell whether the way in which blue things look to me might not be how yellow things look to someone else, and vice versa

(see Locke, 1975: 389). Locke's answer is that it simply doesn't matter, for the purpose of the successful communication of thoughts between people concerning blue or yellow things. However, one might agree with Locke about this while failing to see how he was in a position to say it himself, given his commitment to an ideational theory of linguistic signification. For one might suppose that such a theory takes success in communication to consist in the *replication* in the hearer's mind of ideas which the speaker associates with the words that he or she utters. But there is no reason to tie ideationism to such a doctrine, nor any evidence that ideationists such as Locke espoused it. Ideationism is at most committed to the thesis that in successful communication of the speaker's thoughts to a hearer, ideas are evoked in the hearer's mind which *correspond* to those in the speaker's mind, in a sense of 'correspondence' which does not imply resemblance or replication. That such a correspondence obtains is subject to intersubjective confirmation without imposing upon the persons concerned the impossible burden of comparing each other's ideas, and it may be taken to be set up through the social processes of language teaching and learning (see Lowe, 1996: 172–177).

Identity and Sameness: Philosophical Aspects

H W Noonan, University of Nottingham,
Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

'Identity' and 'sameness' mean the same; their meanings are identical. However, they have more than one meaning. A distinction is customarily drawn between **qualitative** and **numerical** identity and sameness. Things with qualitative identity share properties; so things can be more or less qualitatively identical. Poodles and Great Danes are qualitatively identical because they share the property of being a dog, but two poodles will (very likely) have greater qualitative identity. Numerical identity, however, is not a matter of more or less. Numerical identity requires absolute qualitative identity and can hold only between a thing and itself. Its name implies the controversial view that it is the only identity relation in accordance with which we can properly count (or number) things or at least that so counting has a special status: *x* and *y* are to be counted as one just in case *x* is numerically identical with *y*.

Numerical identity is our topic. It is at the center of various philosophical puzzles but seems to many to be utterly unproblematic – for what could be less problematic than the notion just characterized: that of the relation that everything has to itself and to nothing else? A possible resolution of this apparent paradox (Lewis, 1986) is that there are indeed genuine puzzles stated in the language of numerical identity, but they are not genuinely puzzles about identity, as they can be restated not using it. Philosophical debates about identity of which this is not true are just confusions.

The Logic of Identity

Numerical identity can be characterized, as just done, as the relation everything has to itself and to nothing else. But this is circular, because 'nothing else' just means 'no numerically non-identical thing.' It can be defined, equally circularly, as the smallest equivalence relation (an equivalence relation being one that is reflexive, symmetric, and transitive). Other circular definitions are available. Usually it is explained as the equivalence relation satisfying Leibniz's Law, the principle of the indiscernibility of identicals, that if *x* is identical with *y* then everything true of *x* is true of *y*. Intuitively this is right, but only satisfactory if 'what is true of *x*' is understood to include 'being identical with *x*'; otherwise, it is too weak to serve uncontroversially as a unique characterization of

identity. Circularity is thus not avoided. The converse of Leibniz's Law, the principle of the indiscernibility of identicals, that if everything true of *x* is true of *y*, *x* is identical with *y*, is correspondingly trivial if 'what is true of *x*' is so understood, but with 'what is true of *x*' restricted, e.g., to qualitative, non-relational properties, becomes philosophically controversial.

Leibniz's Law itself has been subject to controversy in the sense that the correct explanation of apparent counterexamples has been debated. It is informative to be told that Hesperus is Phosphorus, but not that Hesperus is Hesperus (Frege, 1969); Giordano was so-called because of his size, Barabelli was not (Quine, 1963). Are these not cases in which something is true of *x* (Hesperus, Giordano) but not of the identical *y*? No. The cases only illustrate the need for distinguishing Leibniz's Law from the principle of substitutivity: if '*x*' and '*y*' are co-designators they are substitutable everywhere without change of truth-value. The cases are not counterexamples to Leibniz's Law, but how best to explain such failures of substitutivity is debatable.

Relative and Absolute Identity

The view that characterizes identity as the equivalence relation that everything has to itself and nothing else and that satisfies Leibniz's Law may be called the classical view. These formal properties ensure that within any theory expressible by means of a fixed stock of one- or many-place predicates, quantifiers and truth-functional connectives any two predicates that can be regarded as expressing identity will be extensionally equivalent. They do not, however, ensure that a two-place predicate does express identity within a particular theory, for it may simply be that the descriptive resources of the theory are insufficiently rich to distinguish items between which the equivalence relation it expresses holds (Geach, 1972). For example, 'has the same income as' will satisfy these conditions in a theory whose descriptive resources do not enable one to distinguish persons with the same income (by not containing, e.g., the predicates 'is male,' 'is female').

Following Geach, call a two-place predicate with these formal properties in some theory an 'I-predicate' relative to that theory. Relative to a richer theory the same predicate, identically interpreted, may not be an I-predicate. If so it will not, and did not even in the poorer theory, express identity.

Quine has suggested that when a predicate is an I-predicate in a theory only because the language is

limited, its sentences always can be reinterpreted so that the I-predicate in the newly interpreted theory does express identity. Each sentence will retain its truth-conditions, but the references of its subsentential parts will be different. Thus, Quine suggests, in a language that cannot distinguish possessors of the same income the predicates may be reinterpreted so that the predicate that previously expressed **having the same income** expresses identity. Correspondingly, there will be a shift in the ontology of the theory (from people to income groups) (Quine, 1963).

This situation provides the basis for one philosophical controversy about identity, whether identity is relative. Geach maintains that as no criterion can be given by which a predicate expressing an I-predicate may be determined to express, not merely indiscernibility relative to the language, but absolute indiscernibility, we should jettison the classical notion of identity (Geach, 1991). Others, following Quine, regard classical identity as an always-legitimate interpretation of an I-predicate and indispensable to our understanding of quantification (Quine, 1963; Dummett, 1991; Hawthorne, 2003).

Another, related, question, is whether numerical identity deserves its name. The procedure we use in counting is as follows: assign '1' to an object *x* and to whatever bears *R* to it and to nothing else, assign '2' to an object *y* to which '1' has not been assigned, to whatever bears *R* to it and to nothing else. . . . The number arrived at will be the number of objects in the domain counting by *R*. If *R* is an equivalence relation this procedure will yield a unique result. If *R* is not numerical identity a larger count will be possible using numerical identity, but if *R* is numerical identity no larger count will be possible. Thus, things related by numerical identity have to be counted as one, whereas things related by weaker equivalence relations can be, but need not be, counted as one. So if numerical identity, classically characterized, is ever an intelligible interpretation of an I-predicate, it deserves its name.

Criteria of Identity

Leibniz's Law characterizes identity but provides no means of recognizing it – we cannot ever determine that *x* is *y* by first of all checking that everything true of *x* is true of *y*. Thus, we apply **criteria** of identity, standards by which identity is to be judged. Different kinds of thing have different criteria of identity and criteria of identity themselves have different logical forms. One distinction is between one-level and two-level criteria of identity (Williamson, 1990) for objects. The criterion of identity for numbers is two-level. The number of *F*s is the number of

*G*s if and only if a one-one correlation exists between the concept *F* and the concept *G*. Numbers are the objects for which the criterion is stated but the condition is given as a relation not on those objects but on concepts (Frege, 1950). By contrast, the criterion of identity for sets given by the Axiom of Extensionality (sets are the same if they have the same members) and Davidson's (1980) criterion of event identity (events are the same if they have the same causes and effects) are one-level, the condition is given as a relation on the very objects for which the criterion is stated. Not all criteria of identity can be two-level. But it does not follow that the only legitimate notion of a criterion of identity remaining is that of a one-level criterion. Another option (Dummett, 1981) is to deny that a criterion of identity must be regarded as a criterion of identity for a type of **object**. At a basic level, on this view, what a criterion of identity is a criterion for, is the truth of a statement in which **no** reference to objects occurs. Such a statement may be expressed using demonstratives, for instance, by saying, 'This is the same cat as that,' pointing first to a tail and then a head. In this the demonstratives need not be construed as referring to objects anymore than reference is made to objects in a feature placing sentence such as, 'It's cold here' or 'It's colder here than there.'

Identity over Time

Criteria of identity can be employed synchronically, as in the example just given, or diachronically, to determine identity over time. Identity over time is a controversial notion, however, because time involves change. Heraclitus argued that one could not bathe in the same river twice because new waters were ever flowing in. Hume argued that identity over time was a fiction we substitute for a collection of related objects. Such views can be seen as based on a misinterpretation of Leibniz's Law: if a thing changes something is true of it at the later time that is not true of it at the earlier, so it is not the same. The answer is that what is true of it at the later time is, say, 'being muddy at the later time,' which was always true of it; similarly, what is true of it at the earlier time, suitably expressed, remains true of it. But the question remains of how to characterize identity across time through change given that such identity exists. On one view, a persisting object is to be thought of as perduring, having different temporal parts at different times, on another it is to be thought as enduring, existing at different times in its entirety (Lewis, 1986). On the former view, temporary qualities like being muddy are genuinely qualities but are possessed by the temporal parts of the persisting object, not the

object itself. On the latter view, they are relations in disguise, relations that the persisting object stands in to different times.

Contingent Identity

Another controversy about identity is whether it can obtain contingently. Of course, there are contingently true identity statements – ‘Benjamin Franklin was the first Postmaster General of the United States’ – but Kripke (1980) argued that when the expressions flanking the identity sign were rigid designators designating the same object across all possible world (unlike ‘the first Postmaster General’) the identity statement had to be necessarily true, if true at all. Relatedly, he argued that identity itself was a necessary relation.

But some examples suggest that this conclusion is too sweeping – that even identity statements containing rigid designators may be, in a sense, contingently true. Consider a statue, Goliath, and the clay, Lump, from which it is composed (Gibbard, 1975). Imagine that Lump and Goliath coincide in their spatio-temporal extent. It is tempting to conclude that they are identical. But they might not have been. Goliath might have been rolled into a ball and destroyed, Lump would have continued to exist. The two would have been distinct.

The debate over contingent identity is concerned with the proper analysis of such examples.

Vague Identity

Like the impossibility of contingent identity, the impossibility of vague identity appears to be a straightforward consequence of the classical concept of identity (Evans, 1978). For if *a* is only vaguely identical with *b*, something is true of it – that it is only vaguely identical with *b* – that is not true of *b*, so by Leibniz’s Law, it is not identical with *b* at all. Of course, there are vague statements of identity – ‘Princeton is Princeton Borough’ (Lewis, 1988; ‘Princeton’ is indeterminate in denotation in standard usage between the township and the borough) – but the conclusion appears to follow that such vagueness is only possible when one or both of the terms flanking the identity sign is an imprecise designator. Relatedly, it appears to follow that identity itself must be a determinate relation.

But some examples suggest that this conclusion is too sweeping – that even identity statements

containing precise designators may be, in some sense, indeterminate. Consider Everest and some precisely defined hunk of rock, ice and snow, ‘Rock,’ of which it is indeterminate whether its boundaries coincide with those of Everest. It is tempting to think that ‘Everest’ and ‘Rock’ are both precise designators (if ‘Everest’ is not is anything?) and that ‘Everest is Rock’ is nonetheless in some sense indeterminate (Tye, 2000).

The debate over vague identity is concerned with the proper analysis of such examples.

Immunity to Error through Misidentification

K Romdenh-Romluc, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Suppose I overhear a conversation and so come to believe the fact in (1).

- (1) Ernie owns a poodle.

Two simple errors I may make are these: I may be mistaken because Ernie owns a greyhound. If so, I have predicated the wrong thing of Ernie. Or I may be mistaken because it is Bert who owns the poodle. In this case I have misidentified the poodle's owner. The latter is called an error of misidentification. To say that an utterance is immune to error through misidentification (IEM) is to say that this sort of mistake has been ruled out. If I see a dog in front of me and so form the belief in (2), I cannot be wrong about *which* dog my judgment is about (although I can make other sorts of mistakes – perhaps the dog is not a highland terrier, or perhaps I am hallucinating and there is no dog).

- (2) That dog is a highland terrier.

Whether or not an utterance about something is IEM depends on how the utterer is thinking about that thing and how he or she has come to know facts about it. The phenomenon interests philosophers because certain 'I'-utterances are IEM, and since many writers take 'I'-utterances to express first-person thoughts, it seems that this fact can shed light on first-person thinking. The next section explains how someone must think about/come to know about *x* for an utterance about *x* to be IEM. In a later section, the main positions in the debate about IEM 'I'-utterances are presented.

IEM

There are different ways for an utterance to be IEM. To come to grips with the phenomenon, we first need to understand what it is for an utterance to be *open* to this kind of error (OEM). In the first example, if the poodle belongs to Bert, I make an error of misidentification when I judge (1), because I mistake Ernie for the poodle's owner. In other words, I judge that Ernie is numerically identical with the owner of the poodle, and my judgment is false, because the person who owns the poodle is Bert. Thus we can see that an error of misidentification consists in mistakenly judging that one thing is numerically identical to another, and it is primarily judgments of numerical identity, as in (3), that are OEM.

- (3) The person who wrote *Crime and Punishment* is Dostoevsky.

Some subject-predicate judgments are also OEM. This is because they depend on judgments of numerical identity (Evans, 1982: 180). Suppose that I see a llama standing in a field and wearing a blue blanket and make the subject-predicate judgment in (4).

- (4) My sister's llama is wearing a blue blanket.

That, in turn, depends on two further judgments. One is a perceptual-demonstrative judgment about *that* llama (the one I can see), as in (5).

- (5) That llama is wearing a blue blanket.

The other is a judgment of numerical identity, as in (6).

- (6) That llama is my sister's llama.

If (6) is false, in judging (4), I will misidentify the llama that is wearing a blue blanket. Hence, (4) is OEM, because it depends on (6).

Since a judgment will be OEM if it either is or depends upon a judgment of numerical identity, it follows that a judgment will be IEM if it is not of these types. There are many different kinds of judgments that are IEM. However, discussion in the literature tends to focus on IEM subject-predicate judgments. These are perceptual-demonstrative judgments – i.e., judgments that are wholly based on direct awareness of the thing the judgment is about, as in (5).

- (5) That llama is wearing a blue blanket.

It is clear that (5) is IEM – I cannot be wrong about *which* llama is wearing a blue blanket (although my judgment can go wrong in other ways, e.g., if the blanket is not blue, there is no blanket, or there is even no llama). The example in (5) is IEM because I both identify the object of the judgment (the llama) and come to know that it is wearing a blue blanket on the basis of my seeing it in the field. As a result, (5) does not depend upon a judgment of numerical identity, and so the possibility of error through misidentification has been ruled out.

IEM 'I'-Utterances

Philosophers are primarily interested in IEM because some 'I'-utterances are IEM. It seems, e.g., impossible to utter the sentence in (7) and be mistaken about *which* person is in pain.

- (7) I am in pain.

It is widely held that 'I'-utterances express first-person thoughts. If this is so, then the fact that some

are IEM can shed light on the nature of first-person thinking, and the self. Nearly all writers accept that some 'I'-utterances are IEM (see, however, Campbell, 1999), but the source of this immunity is disputed.

What is perhaps the most influential account of IEM 'I'-utterances assimilates them to perceptual-demonstrative judgments. Those 'I'-utterances that are IEM appear to express subject-predicate judgments. When I utter (7), I seem to be saying that some object (myself) satisfies the predicate 'in pain'. We see in the first section of this article that a subject-predicate judgment will be IEM if it is wholly based on direct awareness of the thing the judgment is about. Many writers are thus led to conclude that an utterance such as (7) is IEM because it is wholly based on direct awareness of oneself – I observe myself and observe that I am in pain. These writers thereby treat 'I' as a perceptual-demonstrative comparable to terms such as 'this' and 'that' (note, however, that these terms also have uses that are not perceptual-demonstrative). But 'I' does not behave like other perceptual-demonstrative terms. I can use a term such as 'that' to refer to lots of different things; sometimes an utterance of 'that' will fail to refer to anything – e.g., if I hallucinate a llama before me, my attempts to refer to it using 'that' will fail. In contrast, it is traditionally claimed that I can only refer to myself using 'I,' and 'I' cannot fail to refer. Thus, the self-awareness that underlies 'I'-utterances that are IEM cannot be like ordinary forms of observation. First, I use a perceptual-demonstrative term such as 'that' to refer to something I currently see. 'That' can be used to refer to lots of different things, because I can see many entities. If 'I' is a perceptual-demonstrative that can be used to refer only to oneself, it follows that its use must be based on awareness one can have only of oneself. Second, perceptual-demonstratives can fail to refer because we can have illusory experiences, where we seem to perceive an object that is not in fact there. Since 'I' cannot fail to refer, the awareness that underlies its use must not allow for the possibility of complete hallucination in this way.

Various objections to the perceptual-demonstrative account of IEM 'I'-utterances have been raised. Anscombe (1981) objected that the only sort of awareness that could fit the bill would be introspection of a nonphysical self. This claim creates trouble for the view that IEM 'I'-utterances should be treated as perceptual-demonstrative judgments because theorists these days take the self to be a physical entity. A further problem was raised by Shoemaker (1968). On the perceptual-demonstrative view, I make an utterance like (9) on the basis of direct awareness

of the thing the judgment is about – myself. However, Shoemaker argued that observing a self and noticing that it is in pain only allows me to judge (8) in the same way that observing a llama and noticing that it is wearing a blue blanket allows me to judge (5).

(8) That self is in pain.

(5) That llama is wearing a blue blanket.

But (8) is clearly not equivalent to (7). First-person thoughts have a special role in bringing about action (see **Essential Indexical**). I may, e.g., see myself reflected in a shop window, notice that the person I see reflected is standing in the way of the street sweeper, and so judge (9).

(9) That person is obstructing the street sweeper.

But even if I am cooperative, I will not move out of the way unless I believe (10).

(10) I am obstructing the street sweeper.

If observing a self and noticing that it is in pain allows me only to judge (8), to judge (7), I will have to make the judgment of numerical identity (11).

(8) That self is in pain.

(7) I am in pain.

(11) I am that self.

It is unclear on what basis I could judge (11). Moreover, as we have seen, if a subject-predicate judgment depends upon a judgment of numerical identity, then it is OEM. It follows that if I judge (7) on the basis of (8) and (11), then (7) will be OEM. But (7) is IEM; thus, I cannot judge (7) on the basis of (8) and (11). Shoemaker concluded, therefore, that IEM 'I'-utterances cannot be based on self-observation.

Evans (1982) attempted to give a perceptual-demonstrative account of IEM 'I'-utterances that did not fall prey to these objections. We have seen that 'I' differs from other perceptual-demonstrative terms in that I can refer only to myself using 'I,' and 'I' cannot fail to refer. It follows that IEM 'I'-utterances must be based on a form of awareness that one can have only of oneself and that does not allow for hallucination in the same way as a sense like vision, where I can seem to see an object that is not there. Evans suggested that proprioception – the 'inner' sense of one's body, its temperature, limb position, movements, etc. – satisfies both of these conditions. Indeed, it gives rise to 'I'-utterances that are seemingly IEM. If, e.g., I feel that my legs are crossed and utter (12), I surely cannot be wrong about which person has their legs crossed.

(12) I have my legs crossed.

Evans held that all IEM 'I'-utterances are based upon proprioceptive experience of one's body.

Anscombe objected to the perceptual-demonstrative account of IEM 'I'-utterances, because it seemed that only introspection of a nonphysical self could satisfy the relevant conditions. Evans's account silenced this objection, because proprioception is awareness of one's body. It could also deal with the worry raised by Shoemaker. Shoemaker claimed that observation of a self could license only a judgment such as (8), rather than (7).

(8) That self is in pain.

(7) I am in pain.

Judgments (7) and (8) are not equivalent, because they have different implications for action. One might think that Shoemaker could make the same objection to Evans's account: proprioceptive experience allows me only to judge, e.g., (13) and not the first-person judgment (12).

(13) That body has its legs crossed.

(12) I have my legs crossed.

However, proprioceptive experience allows us to act unreflectively on the information given in that experience. Suppose that I feel a mosquito crawling on my arm; I can immediately slap my arm without thinking about doing so. In particular, I do not need to identify the arm I can feel the mosquito crawling along as *my* arm. The way in which proprioceptive awareness has an immediate bearing on my actions suggests that it is awareness that is distinctively first-personal. It follows that it can license a first-person judgment such as (12), not merely a judgment such as (13). Thus, Evans's account does not fall prey to Shoemaker's objection.

Evans's account, however, is not free from problems. It is perhaps conceivable that I could have proprioceptive experience of another's body if my brain were appropriately 'wired' to their limbs. In such a case I might judge (14).

(14) I have an itch in my left foot.

But since my proprioceptive experience comes from their body, not mine, in judging (14), I misidentify the person whose left foot is itchy. Examples such as this are famously taken to show that judgments based on proprioceptive awareness of one's body are not IEM.

Wittgenstein, who is credited with first noticing that certain 'I'-utterances are IEM, gives a radically different analysis of such utterances. To understand his account, we need to distinguish between

utterances and judgments. I have so far spoken as if they are interchangeable. In many cases this is acceptable, because utterances are often used to express judgments. Suppose I am asked a question in class and answer (15).

(15) The capital of England is London.

My utterance expresses a judgment that London is the capital of England – by uttering (15), I express my commitment to the existence of a particular country, the existence of a particular city, and the obtaining of a particular relation between them. However, not all utterances express judgments. Suppose that I utter (16) as the punch line of a joke.

(16) John's donkey is drunk.

Unlike (15), (16) does not express a judgment – I am not committed to the existence of John or his donkey. Since an error of misidentification consists in mistakenly judging that one thing is numerically identical to another, if I make an utterance that expresses no judgment, my utterance will be IEM. When I utter (16), I am not committing myself to the existence of some particular donkey, which I believe to be drunk. It thus makes no sense to suppose that I could misidentify the donkey in question.

Wittgenstein (1953) accounted for the IEM status of certain 'I'-utterances in this way. He argued that some present-tense 'I'-utterances that involve psychological predicates, such as (17), cannot be understood as expressing judgments.

(17) I feel dazed.

Instead, we should think of them as expressing one's psychological states in much the same way that groaning sometimes expresses pain. 'I'-utterances of this sort are IEM; they have this status, according to Wittgenstein, because they do not express judgments. A consequence of this view is that 'I,' as it is used in these utterances, does not refer to anything. It makes no sense to talk of a groan as having a referent. Since utterances like (17) express psychological states in the same kind of way that groaning sometimes expresses pain, 'I' as it is used in (17) does not refer to anything. Most have dismissed Wittgenstein's 'no-reference thesis,' as this view is called. It is also unclear how IEM 'I'-utterances involving *physical* predicates (assuming that there are such utterances) should be treated on the Wittgenstein picture. Suppose a particular bodily sensation prompts me to utter (12).

(12) I have my legs crossed.

It is unclear how (12) could be treated as expressing a state in the same way that groaning can be understood as expressing pain.

Implicature

J Meibauer, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Basic Notions

The term '*implicature*' goes back to the philosopher Paul Grice, as laid down in his seminal article 'Logic and Conversation' (Grice, 1989), which is the published version of a part of his William James lectures held in 1967 at Harvard University. In Grice's approach, both 'what is implicated' and 'what is said' are part of speaker meaning. 'What is said' is that part of meaning that is determined by truth-conditional semantics, while 'what is implicated' is that part of meaning that cannot be captured by truth conditions and therefore belongs to pragmatics. Several types of implicature are distinguished. **Figure 1** shows the

Figure 1 Gricean typology of speaker meaning.

Gricean typology of speaker meaning (cf. Levinson, 1983: 131).

The most widely accepted type of implicature is the *conversational implicature*. According to Grice, it comes in two ways, generalized conversational implicature (GCI) and particularized conversational implicature (PCI). The following example from Levinson (2000: 16–17) illustrates this distinction:

- Context, 1** Speaker A: What time is it?
 Speaker B: Some of the guests are already leaving.
 PCI: 'It must be late.'
 GCI: 'Not all of the guests are already leaving.'
- Context, 2** Speaker A: Where's John?
 Speaker B: Some of the guests are already leaving.
 PCI: 'Perhaps John has already left.'
 GCI: 'Not all of the guests are already leaving.'

Because the implicature ('... not all ...') triggered by *some* arises in both contexts, it is relatively context-independent. Relative context-independence is the most prominent property of GCIs. In addition, GCIs are normally, or even consistently, associated with certain linguistic forms. For example, if someone utters *Peter is meeting a woman this evening* it is, because of the indefinite article, standardly implicated that the woman is not his wife, close relative,

etc. (cf. Grice, 1989: 37; Hawkins, 1991). In contrast to GCIs, PCIs are highly context-dependent, and they are not consistently associated with any linguistic form.

The distinction between conversational implicatures and *conventional implicatures* draws on the observation that in coordinations like *Anna is rich but she is happy*, the truth conditions are just the truth conditions of the coordination *Anna is rich and she is happy*, with the exception of the contrastive meaning of *but*. This meaning is not truth-functional, and it is not context-dependent either; hence, there is some motivation for assuming the category of conventional implicature.

Note that there may be further types of implicature, e.g., implicatures of politeness or style that are neither conventional nor conversational (cf. Leech, 1983; Brown and Levinson, 1987).

Conversational implicatures come about by the *exploitation* (apparent flouting) or *observation* of the *cooperative principle* (CP) and a set of maxims (Grice, 1989) (see **Cooperative Principle; Maxims and Flouting**):

Cooperative Principle

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged.

Maxim of Quantity

1. Make your contribution as informative as is required (for the current purposes of exchange).
2. Do not make your contribution more informative than is required.

Maxim of Quality

Try to make your contribution one that is true.

1. Do not say what you believe to be false.
2. Do not say that for which you lack adequate evidence.

Maxim of Relevance

Be relevant.

Maxim of Manner

Be perspicuous.

1. Avoid obscurity of expression.
2. Avoid ambiguity.
3. Be brief (avoid unnecessary prolixity).
4. Be orderly.

These maxims and submaxims are conceived as rules of rational behavior, not as ethical norms. They figure prominently in the derivation of an implicature. The basic idea of such a derivation is best illustrated with a simple dialogue. Imagine that I ask my colleague *Is Markus there?* and she answers *There is a pink Porsche behind the library building*. Understood

literally, such an answer does not make any sense. However, as I assume that my colleague is cooperative, and remembering that Markus drives a pink Porsche, I can figure out that Markus is in the library. In working out this information, I have made use of the assumption that my colleague's answer has been relevant with regard to my question. Thus, conversational implicatures display the property of *calculability*. A general scheme for the working out of a conversational implicature is given by Grice (1989: 30–31):

A man who, by (in, when) saying (or making as if to say) that *p* has implicated that *q*, may be said to have conversationally implicated that *q*, provided that (1) he is to be presumed to be observing the conversational maxims, or at least the Cooperative Principle; (2) the supposition that he is aware that, or thinks that, *q* is required in order to make his saying or making as if to say *p* (or doing so in *those* terms) consistent with this presumption; and (3) the speaker thinks (and would expect the hearer to think that the speaker thinks) that it is within the competence of the hearer to work out, or grasp intuitively, that the supposition in (2) is required.

Table 1 lists some of the most typical cases covered by the CP and the maxims. Examples for each case are given below the table. For further classical examples, see Grice (1989) and Levinson (1983). In what follows, '+>' stands for 'implicates conversationally':

- (1) War is war. +> 'There is nothing one can do about it.'
- (2) Some men were drunk. +> 'Not all of them were drunk.'
- (3a) He is a fine friend. +> 'He is not a fine friend.'
- (3b) You are the cream in my coffee. +> 'You are my best friend.'
- (4) There is life on Mars. +> 'Speaker believes that there is life on Mars.'
- (5) Speaker A: I'm out of petrol.
Speaker B: There is a garage round the corner.
+> 'The garage is open.'

Table 1 Typical cases of implicature

Maxims	Exploitation	Observation
Quantity	Tautology (1)	Scalar implicature (2)
Quality	Irony, metaphor, sarcasm (3)	Belief implicature in assertions (4)
Relevance	Implicatures due to thematic switch (5)	Bridging (6)
Manner	Implicatures due to obscurity, etc. (7)	Conjunction buttressing (8)

- (6) Speaker A: Look, that old spinster over there!
 Speaker B: Nice weather today, isn't it? +> 'No comment.'
- (7) She produced a series of noises that resembled
 "Si, mi chiamano Mimi". +> 'Her singing was
 a complete disaster.'
- (8) Anna went to the shop and bought jeans. +> 'She
 bought the jeans in the shop.'

For further illustration of the exploitation/observation dichotomy, look at (1) and (8). As to (1), tautological utterances are always true, which amounts to their being fundamentally uninformative. There is no situation where a speaker wants to tell someone that something is identical with itself. Thus, it seems that the utterer of (1) has violated the first maxim of Quality. Gricean reasoning then leads the hearer to the insight that this violation was only apparent (cf. Autenrieth, 1997). In (8), we have a simple conjunction of two sentences. If the meaning of *and* were to be the same as the meaning of the logical operator, it could not be explained that there is an additional meaning 'and then.' Grice's view is that we may identify the semantic meaning of *and* with the pure connecting operation known from logic as long as we are able to derive the additional meaning from the maxims. The observation of the fourth maxim of Manner, "Be orderly!", will do this job (cf. Posner, 1980). Both observation and exploitation are in line with the general pattern for working out an implicature.

Besides the property of calculability, conversational implicatures display the properties of variability and cancellability. *Variability* means that there are contexts where the speaker utters the same utterance, but the respective implicature does not arise. Thus, the implicature is dependent on the specific context in which it arises. (This does not exclude the notion of relative context-independency in the case of GCIs.) *Cancellability* (or defeasibility) means that it is possible to withdraw an implicature within the situation of utterance without any contradiction. For example, it is possible to utter *Some men were drunk, indeed all*. Reversely, conversational implicatures should be *reinforceable*, as Sadock (1978) proposed. Thus, it is possible to conjoin the content of an implicature with the utterance that triggers that implicature, as in *Some of the girls were reading books but not all*.

Conventional implicatures are neither calculable, nor variable, nor cancellable. However, they are said to be detachable, i.e., if the elements that trigger them are replaced, the respective implicature does not arise. By contrast, conversational implicatures are *non-detachable*, i.e., if there is an expression X' that shares meaning with expression X that triggers the implicature, the same implicature should arise. For example,

if *She is very beautiful* gives rise to an ironical implicature, then *She is a real beauty* should have the same effect (Sadock, 1978: 287). (An obvious exception to this are Manner implicatures.)

For further illustration, consider focus particles like *even*. An utterance such as *Even JOHN drives a Porsche* has the same truth conditions as the corresponding utterance without the focus particle, i.e., *John drives a Porsche*. The additional meaning of the type 'John is the least likely to drive a Porsche,' being related to a contextually given set of other individuals (e.g., Gustav, Bettina, Markus...), may be considered as a conventional implicature (cf. König, 1991), because this meaning appears to be neither truth-conditional nor context-dependent. Moreover, if *even* is replaced by another focus particle, the respective implicature is not triggered. However, if the conventional implicature is bound to the specific lexical item *even*, and for this reason is detachable, then the implicature seems to be part of the literal meaning of this lexical item. Therefore, it is difficult to distinguish between conventional implicatures on the one hand and entailments (belonging to the 'what is said') on the other hand. For this and other reasons, some researchers do not accept that there is a category of conventional implicature (cf. Bach, 1999; for a logical approach, see Potts, 2005).

Beyond Grice

The reception of the Gricean framework has been largely dominated by the wish to develop a more systematic architecture of maxims. Moreover, the Cooperative Principle has been on trial, as other aspects (e.g., logical, anthropological, cognitive, etc.) became more attractive. The prevailing tendency has been to reduce the set of maxims proposed by Grice. Three major reductive approaches have been developed: (a) the tri-heuristic approach by Levinson (2000), (b) the dual principle approach by Horn (1984), and (c) the monoprincipled approach by Sperber and Wilson (1995) and Carston (2002). These approaches are outlined in the following sections. It should be mentioned, however, that there are other important approaches that elaborate on the Gricean framework, e.g., Gazdar (1979) or Atlas (2005), as well as radical criticisms such as Davis (1998). For useful surveys, see Levinson (1983: Ch. 3) and Rolf (1994).

Presumptive Meanings: Levinson's Theory of Generalized Conversational Implicature

Levinson develops his revision of Grice's maxims from three heuristics that follow from the

anthropological need to overcome the “fundamental bottleneck in the efficiency of human communication, occasioned no doubt by absolute physiological constraints on the articulators” (Levinson, 2000: 28). Accordingly, Grice’s rationalistic CP plays no role. The heuristics are (Levinson, 2000: 31–33):

Levinson’s Heuristics

Heuristic 1: What isn’t said, isn’t.

Heuristic 2: What is simply described, is stereotypically exemplified.

Heuristic 3: What’s said in an abnormal way, isn’t normal; or Marked message indicates marked situation.

Heuristics 1 corresponds to Levinson’s Q-principle (see maxim of Quantity 1 in Grice’s framework), Heuristics 2 to Levinson’s I-principle (Grice’s maxim of Quantity 2), and Heuristics 3 to Levinson’s M-principle (Grice’s maxim of Manner 1 and 3). These three principles are said to derive GCIs. For the correspondences to Grice, and a typical example, see Table 2.

Where inconsistent implicatures arise, they are “systematically resolved by an ordered set of priorities” (Levinson, 2000: 39), among them $Q > M > I$, where ‘>’ is understood as ‘defeats inconsistency.’ Levinson (2000: 153–164) gives some examples for $Q > I$, $Q > M$, and $M > I$. An example for $Q > M$ is *It’s not unlikely that Giant Stride will win the Derby, and indeed I think it is likely*. Here, as Levinson (2000: 160) points out, the first conjunct gives rise to the M-based implicature ‘less than fully likely,’ because of the double negative *not unlikely*, while the second conjunct triggers the Q-based implicature ‘it is possible it is likely,’ because of the use of *think*, which does not entail the complement clause. In this case, the Q-implicature of the second conjunct defeats the M-implicature of the first. (However, as Traugott, 2004: 11 observes, *indeed* may serve as a M-implicature cancelling device.)

The Q-principle is defined as follows (Levinson, 2000: 76):

Q-principle

Speaker’s maxim: Do not provide a statement that is

informationally weaker than your knowledge of the world allows, unless providing an informationally stronger statement would contravene the I-principle. Specifically, select the informationally strongest paradigmatic alternate that is consistent with the facts.

Recipient’s corollary: Take it that the speaker made the strongest statement consistent with what he knows, and therefore that:

a. if the speaker asserts $A(W)$, where A is a sentence frame and W an informationally weaker expression than S , and the contrastive expressions $\langle S, W \rangle$ form a Horn scale (in the prototype case such that $A(S)$ entails $A(W)$), then one can infer that the speaker knows that the stronger statement $A(S)$ (with S substituted for W) would be false [...]

b. if the speaker asserted $A(W)$ and $A(W)$ fails to entail an embedded sentence Q , which a stronger statement $A(S)$ would entail, and $\{S, W\}$ form a contrast set, then one can infer that the speaker does not know whether Q obtains or not (i.e., $\{P(Q), P \sim (Q)\}$ read as ‘it is epistemically possible that Q and epistemically possible that not- Q ’)

The I-Principle mentioned in the Speaker’s maxim requires that a speaker should not be more informative than necessary (see below). Wherever it is possible, the speaker should build on stereotypical assumptions. In the Recipient’s corollary, two cases are distinguished, namely scalar implicature, involving Horn scales (named after Laurence Horn, see the next section) and clausal implicature, involving contrast sets.

In the case of *scalar implicatures*, we need a *Horn scale*: given a scale $\langle q, p \rangle$ with p as an informationally weak and q as an informationally strong element, the assertion of p implicates the negation of q . In such cases, the speaker is supposed to be as informative as possible, thus observing the Q-principle (or the maxim of Quantity). Therefore, the speaker could not say more than he actually did, and this means that the stronger statement does not hold. A classical example is the utterance $p = \text{Some colleagues were drunk}$ implicating $q = \text{‘Not all of them were drunk’}$. In the case of *clausal implicatures*, we need *contrast sets*. Let $\{\text{know}, \text{believe}\}$ be a contrast set. Then $p = \text{The doctor believes that the patient will not recover}$ implicates $q_1 = \text{‘The doctor may or may not know$

Table 2 Correspondences between Levinson’s Heuristics and Principles, and Grice’s Maxims

Heuristics	Principles	Grice’s Maxims	Example
Heuristic 1	Q-Principle	Quantity, 1	Q-Implicature: (a) Some colleagues were drunk. $+>$ ‘Not all of them were drunk.’ (scalar implicature) (b) The doctor believes that the patient will not recover. $+>$ ‘The doctor may or may not know that the patient will not recover.’ (clausal implicature)
Heuristic 2	I-Principle	Quantity, 2	I-Implicature: Anna turned the switch and the motor started. $+>$ ‘Anna turned the switch and then/therefore the motor started.’ (conjunction buttressing)
Heuristic 3	M-Principle	Manner, 1 and 3	M-Implicature: Bill caused the car to stop. (vs. Bill stopped the car.) $+>$ ‘He did this indirectly, not in the normal way, e.g., by use of the emergency brake.’ (periphrasis)

that the patient will not recover' (Levinson, 2000: 110). The crucial point is that clausal implicatures indicate epistemic uncertainty about the truth of the embedded sentence. Note that, because <know, believe> also form a Horn scale, there is a scalar implicature as well: in this case *p* implicates *q*₂ = 'The doctor does not know that the patient will not recover.'

Well-known Horn scales include the quantifiers <all, most, many, some>, connectives <and, or>, modals <necessarily, possibly>, <must, should, may>, adverbs <always, often, sometimes>, degree adjectives <hot, warm>, and verbs <know, believe>, <love, like>. Contrast sets include verbal doublets like {know, believe}, {realize, think}, {reveal, claim}, {predict, foresee}, and others (cf. Levinson, 2000: 111).

Now consider the I-principle (Levinson, 2000: 114–115):

I-Principle

Speaker's maxim: the maxim of Minimization. 'Say as little as necessary'; that is, produce the minimal linguistic information sufficient to achieve your communicational ends (bearing *Q* in mind).

Recipient's corollary: the Enrichment Rule. Amplify the informational content of the speaker's utterance by finding the most *specific* interpretation, up to what you judge to be the speaker's *m*-intended [= meaning-intended] point, unless the speaker has broken the maxim of Minimization by using a marked or prolix expression.

Specifically:

- a. Assume the richest temporal, causal and referential connections between described situations or events, consistent with what is taken for granted.
- b. Assume that stereotypical relations obtain between referents or events, unless this is inconsistent with (a).
- c. Avoid interpretations that multiply entities referred to (assume referential parsimony); specifically, prefer coreferential readings of reduced NPs (pronouns and zeros).
- d. Assume the existence or actuality of what a sentence is about (if that is consistent with what is taken for granted).

This principle is said to cover a whole range of implicatures: conditional perfection (9), conjunction buttressing (10), bridging (11), inference to stereotype (12), negative strengthening (13), NEG-raising (14), preferred local coreference (15), the mirror maxim (16), specialization of spatial terms (17), and possessive interpretations (18) (cf. Levinson, 2000: 117–118).

- (9) If you mow the lawn, I'll give you five dollars.
+> 'If you don't mow the lawn, I will not give you five dollars.'

- (10) Bettina wrote an encyclopedia and sold the rights to Elsevier. +> 'Bettina wrote an encyclopedia and then sold the rights to Elsevier.'
- (11) Gustav unpacked the picnic. The beer was warm. +> 'The beer was part of the picnic.'
- (12) Markus said 'Hello' to the secretary and then he smiled. +> 'Markus said "Hello" to the female secretary and then Markus smiled.'
- (13) I don't like Alice. +> 'I positively dislike Alice.'
- (14) I don't think he is reliable. +> 'I think he is not reliable.'
- (15) John came in and he sat down. +> 'John_i came in and he_i sat down.'
- (16) Harry and Sue bought a piano. +> 'They bought it together, not one each.'
- (17) The nail is in the wood. +> 'The nail is buried in the wood.'
- (18) Wendy's children +> 'those to whom she is parent'; Wendy's house +> 'the one she lives in'; 'Wendy's responsibility' +> the one falling on her; Wendy's theory +> 'the one she originated'

The M-principle is defined as follows (Levinson, 2000: 136–137):

M-principle

Speaker's maxim: Indicate an abnormal, nonstereotypical situation by using marked expressions that contrast with those you would use to describe the corresponding normal, stereotypical situation.

Recipient's corollary: What is said in an abnormal way indicates an abnormal situation, or marked messages indicate marked situations, specifically:

Where *S* has said *p*, containing a marked expression *M*, and there is an unmarked alternate expression *U*, with the same denotation *D*, which the speaker might have employed in the same sentence-frame instead, then where *U* would have I-implicated the stereotypical or more specific subset *d* of *D*, the marked expression *M* will implicate the complement of the denotation *d*, namely \bar{d} of *D*.

The M-principle is supposed to cover a range of cases, among them lexical doublets (19) and rival word formations (20), nominal compounds (21), litotes (22), certain genitive (23) and zero morph constructions (24), periphrasis (25), and repetition (26) (cf. Levinson, 2000: 138–153).

- (19) She was reading a tome [vs. book]. +> 'She was reading some massive, weighty volume.'
- (20) Ich nehme den Flieger [vs. das Flugzeug].
(= I take the plane [vs. the airplane]) +>
'Fliegen ist nichts Besonderes für mich.'
(= 'Flying is quite normal for me.')

- (21) This is a box for matches (vs. matchbox). +> 'This is a (nonprototypical) box specially made for containing matches.'
- (22) It took a not inconsiderable effort. +> 'It took a close-to-considerable effort.'
- (23) the picture of the child (vs. the child's picture) +> 'the picture depicts the child'
- (24) She went to the school/the church/the university (vs. to school, to church, to university, etc.) +> 'She went to the place but not necessarily to do the associated stereotypical activity.'
- (25) Bill caused the car to stop. (vs. Bill stopped the car.) +> 'He did this indirectly, not in the normal way (e.g., by using the emergency brake).'
- (26) He went to bed and slept and slept. +> 'He slept longer than usual.'

Note that only the first ('Avoid obscurity of expression') and the third ('Be brief (avoid unnecessary prolixity)') submaxims of the Gricean maxims of Manner survive in Levinson's M-principle. Levinson views the second submaxim ('Avoid ambiguity') in connection with 'generality narrowing', which is subsumed under the Q-principle (Levinson, 2000: 135). The fourth submaxim ('Be orderly') is not needed any more, because the notorious cases of 'conjunction buttressing' fall under the I-principle in Levinson's framework. Moreover, Levinson (2000: 135) notes the general cognitive status of this general semiotic principle of linearization, and he questions its status as a maxim.

It seems that many of the cases in (19)–(26) may be explained in terms of the Q- or I-principle; in other cases, it is not at all clear that we have the same denotation, as required in the Recipient's corollary of the M-principle, thus throwing into doubt whether a separate M-principle is really needed. By comparison, Horn's (1984) approach (sketched in the next section) has no separate maxim/principle of Manner. For further discussion, see Meibauer (1997) and Traugott (2004).

Obviously, the maxim of Quality and the maxim of Relevance are not maxims that figure in the derivation of GCIs. The only comment on the maxim of Quality Levinson gives is that this maxim "plays only a background role" in the derivation of GCIs; maybe he has the sincerity conditions for assertive acts in mind (Levinson, 2000: 74). Note that Grice (1989: 34) needed the maxim of Quality to derive the implicatures in the cases of irony, metaphor, and sarcasm (see *Irony*). In contrast, Levinson argues that irony and sarcasm are cases of PCIs (Levinson, 2000: 386, Fn. 2), a claim that seems somewhat premature at least when considering cases

of conventional irony and sarcasm. The maxim of Relevance is a maxim that, according to Levinson (2000: 74), derives only PCIs. However, this maxim seems to play a role when it comes to disambiguation and 'ellipsis unpacking' (Levinson, 2000: 174, 183) (see *Relevance Theory*).

In addition to the revision of the Gricean maxims just outlined, Levinson sketches a radical revision of the widely accepted Gricean view of the interaction of grammar and pragmatics according to which in language production, conversational implicatures are supposed to operate on, and follow the semantic representation of, the said (Levinson, 2000: 173). Levinson finds this view basically wrong:

Grice's account makes implicature dependent on a prior determination of 'the said.' The said in turn depends on disambiguation, indexical resolution, reference fixing, not to mention ellipsis unpacking and generality narrowing. But each of these processes, which are prerequisites to determining the proposition expressed, may themselves depend crucially on processes that look undistinguishable from implicatures. Thus, what is said seems both to determine and to be determined by implicature. Let us call this *Grice's circle*. (Levinson, 2000: 186)

According to Levinson, there are at least five phenomena that show the influence of GCIs on sentence meaning (Levinson, 2000: 172–187). First, GCIs (of the scalar type) are involved in the disambiguation of ambiguous constructions like *some cats and dogs*, for only the bracketing *[[some cats] and dogs]*, with the appropriate implicature 'some but not all cats, and dogs in general,' is appropriate in the sentence *He's an indiscriminate dog-lover; he likes some cats and dogs*. Second, the resolution of indexicals is dependent on the calculation of GCIs, e.g., *The meeting is on Thursday*. +> 'not tomorrow' (when tomorrow is Thursday). Third, reference identification often requires GCIs, e.g., *John came in and the man sat down*. +> 'The man was not identical to John.' Fourth, in ellipsis unpacking, as in simple dialogues like *Who came? – John <came>*, the missing information is constructed on the basis of Relevance and I-Implicature. Finally, there is the case of generality narrowing, e.g., if someone utters *I've eaten breakfast* +> 'I've eaten breakfast [this morning]' where the Q-principle is activated.

In order to resolve the dilemma of Grice's circle, i.e., to account for 'pragmatic intrusion,' Levinson proposes an alternative model (Levinson, 2000: 188). This model contains three pragmatic components, namely Indexical Pragmatics, Gricean Pragmatics 1, and Gricean Pragmatics 2, and two semantic components, namely Compositional Semantics and Semantic Interpretation (model-theoretic

interpretation). The output of Compositional Semantics and Indexical Pragmatics is input for Gricean Pragmatics 1. The output of Gricean Pragmatics 1 is input for Semantic Interpretation, and its output ('sentence meaning, proposition expressed') is input for Gricean Pragmatics 2, whose output is 'speaker meaning, proposition meant by the speaker.'

Whereas Indexical Pragmatics and Gricean Pragmatics 1 are presemantic pragmatic components, Gricean Pragmatics 2 is a postsemantic pragmatic component. It seems that Gricean Pragmatics 2 deals with PCIs ('indirection, irony and tropes, etc.,') whereas Gricean Pragmatics 1 deals with GCIs ('disambiguation, fixing reference, generality-narrowing, etc.,'). At the heart of Levinson's approach is his analysis of GCIs, precisely because it is here that arguments for this new model of the semantics-pragmatics interaction may be found.

Division of Pragmatic Labor: Horn's Q- and R-Principles

Central to Horn's approach to implicature is the insight that implicatures have to do with "regulating the economy of linguistic information" (Horn, 2004: 13). In contrast to Levinson, Horn (1984) assumes only two principles, the Q-principle and the R-principle:

Q-principle

Make your contribution sufficient: Say as much as you can (given R).

(Lower-bounding principle, inducing upper-bounding implicatures)

R-principle

Make your contribution necessary: Say no more than you must (given Q).

(Upper-bounding principle, inducing lower-bounding implicatures)

The Q-principle collects the Gricean maxims of Quantity 1 as well as Manner 1 and 2, while the R-Principle collects Quantity 2, Relation, and Manner 3 and 4. The maxim of Quality is considered as unreducible, as truthfulness is a precondition for satisfying the other maxims (Horn, 2004: 7).

The Q-principle aims at the maximization of content. It is a guarantee for the hearer that the content is sufficient. The hearer infers from the speaker's failure to use a more informative or briefer form that the

speaker was not in a position to do so. Scalar implicatures are a case in point. The R-principle aims at the minimization of expression, and consequently, the minimization of the speaker's effort. According to Horn, this principle holds for all indirect speech acts.

The following table, which is adapted from Horn (2004: 10), shows how the Q-principle works in the case of scalar implicatures (Table 3). The two-sided reading is the default case.

According to Horn, the conflict between the Q-principle and the R-principle may be resolved, as expressed by the following principle (Horn, 1984: 22):

The Division of Pragmatic Labor

The use of a marked (relatively complex and/or prolix) expression when a corresponding unmarked (simpler, less 'effortful') alternative expression is available tends to be interpreted as conveying a marked message (one which the unmarked alternative would not or could not have conveyed).

Levinson (1987: 73) argues that Horn mixes up two things here that properly should be distinguished, namely minimization of content on the one hand, and minimization of expression on the other. According to Levinson, splitting up the maxims of Manner in the way Horn does is mistaken, because the Manner maxims are fundamentally dependent on form, and thus related to minimization of expression.

Following Horn's original work, much research has been done on Horn scales, e.g., by Hirschberg (1991), Fretheim (1992), Matsumoto (1995), Sauerland (2004), van Rooy (2004). In this connection, three further areas of research deserve to be singled out.

First, as shown in Horn (1989: Ch. 4), there is the phenomenon of *metalinguistic negation*. For example, when uttering *It's not warm, it's hot!* the first part of the utterance gives rise to the scalar implicature 'It is not hot,' but this implicature is obviously denied in the second part of the utterance. Typically, utterances of this type have a humorous, ironical, or sarcastic flair (cf. Chapman, 1996 for an overview and Carston, 1996 and Iwata, 1998 for an echo-theoretic interpretation).

Second, there is some discussion about the exact status of the Horn scales in the lexicon, e.g., how are

Table 3 Application of the Q-Principle to scalar implicatures

<i>Statements</i>	<i>Lower bound, one-sided (what is said)</i>	<i>Upper bound, two-sided (what is implicated qua Q)</i>
a. Pat has three children	'... at least three ...'	'... exactly three ...'
b. You ate some of the cake	'... some if not all ...'	'... some but not all ...'
c. It's possible she'll win	'... at least possible ...'	'... possible but not certain ...'
d. He's a knave or a fool	'... and perhaps both ...'	'... but not both'
e. It's warm	'... at least warm ...'	'... but not hot'

elements selected for scales, how is the ordering of the elements achieved, etc. An influential approach is the one by Hirschberg (1991), who argues that there exist, in addition to lexical scales, scales that are induced pragmatically or on the basis of real-world knowledge. For example, when speaker A asks *Did you get Paul Newman's autograph?* and speaker B answers *I got Joanne Woodward's*, implicating 'not Paul Newman's,' we are dealing with a salient scale of autograph prestige <Newman, Woodward>. Consequently, Hirschberg (1991: 42) denies that there is any principled distinction between GCIs and PCIs.

Third, the economical aspect of Horn's reduction of the Gricean apparatus has recently become very attractive within *Bidirectional Optimality Theory* (cf. Blutner, 2004). This theory assumes that sentences are semantically underspecified, and therefore are in need of enrichment. A function *Gen* is assumed that determines for each common ground the set of possible enrichments. Bidirectional (i.e., taking the perspective of speaker *and* hearer) Optimality Theory then stipulates that a form-meaning pair is optimal if and only if it is taken from the set defined by *Gen*, and that there is no other pair that better fulfills the requirements of the Q- and I-principle. For an application and further discussion, see Krifka (2002).

Relevance Theory: Carston's Underdeterminacy Thesis

Relevance theory is a cognitive theory of meaning whose major claims are that semantic meaning is the result of linguistic decoding processes, whereas pragmatic meaning is the result of inferential processes constrained by one single principle, the *Principle of Relevance*, originally proposed in Sperber and Wilson (1995) (see **Relevance Theory**). However, the connection to the Gricean maxim of Relevance is rather weak, as can be seen from the following definitions (Carston, 2002; for other versions, see Wilson and Sperber, 2004):

First (Cognitive) Principle of Relevance

Human cognition is geared towards the maximization of relevance (that is, to the achievement of as many contextual (cognitive) effects as possible for as little processing effort as possible).

Second (Communicative) Principle of Relevance

Every act of ostensive communication (e.g., an utterance) communicates a presumption of its own optimal relevance.

Carston (2002) questions the standard division of labor between semantics and pragmatics and argues that pragmatics contributes much more to the

construction of explicit meaning ('what is said') than generally assumed. Her overall aim is to establish relevance theory as a theory of cognitive pragmatics. The relevance theoretic approach is, according to Carston, "to be characterized as a sub-personal-level explanatory account of a specific performance mechanism conducted at the level of representations-and-procedures" (Carston, 2002: 11).

Carston's *underdeterminacy thesis* says that linguistic meaning generally underdetermines what is said. Pragmatic inferences are not only necessary to determine implicatures, but also to fix the proposition directly expressed by an utterance. This discrepancy between the meaning encoded in linguistic expressions and the proposition expressed by the utterance of these expressions ('what is said') is illustrated by various cases (over and above the well-known cases of ambiguities and indexical resolution): missing constituents (27), unspecified scope of elements (28), underspecification or weakness of encoded conceptual content (29), overspecification or narrowness of encoded conceptual content (30):

- (27a) [Where is the book?] On the top shelf.
(= 'The book is on the top shelf.')
- (27b) Paracetamol is better. [than what?]
- (27c) This fruit is green. [which part of the fruit?]
- (28a) She didn't butter the toast in the bathroom
with a knife. [different stress changes the
information structure]
- (28b) There's nothing on TV tonight. [nothing that is
interesting for you]
- (29) I'm tired. [predicate is too weak]
- (30) Her face is oblong. [predicate is too narrow]

In all these cases, additional inferential steps are necessary to understand what the speaker intends to say.

Since linguistically encoded meanings are necessarily incomplete, pragmatics makes an essential contribution not only to the construction of *implicit meaning* but also to the construction of *explicit meaning*. In the spirit of Relevance Theory, Carston proposes a three-level model of semantic and pragmatic interpretation of linguistic expressions.

The first step involves semantic decoding of linguistic expressions. The output of the semantic decoding is an impoverished, nonpropositional semantic representation, which Carston calls logical form. It can be described as a "structured string of concepts with certain logical and causal properties" (Carston, 2002: 57) containing slots indicating where certain contextual values must be supplied. Hence, the output of the semantic decoding device is an incomplete template or scheme, open to a range of compatible propositions.

In the second step of interpretation, the hearer reconstructs the proposition intended by the speaker through pragmatic inference. Thus, pragmatic inference bridges the gap between what is linguistically expressed (incomplete conceptual schemata/logical form) and what is said (full propositional representations). For example, when a speaker utters the subsentential expression *on the top shelf* in a given context of utterance, the hearer is supposed to reconstruct the missing constituents to yield the intended proposition 'The marmalade is on the top shelf'. The pragmatic interpretation device is constrained by the First (Cognitive) Principle of Relevance, as proposed by Sperber and Wilson (1995).

Finally, there has to be a third step of interpretation, in which the hearer determines implicatures, i.e., 'what is meant.' Thus, Carston assumes that pragmatic inference is necessary for the second and third step of interpretation. In this cognitive approach, the bulk of utterance interpretation has to be done by pragmatic inference.

The pragmatic device of interpretation relies not only on linguistic information but also on additional information gained from context, perception, and world knowledge. Here, Carston essentially refers to Searle's theory of mind, especially his notion of *Background* (cf. Searle, 1980). Utterances are interpreted against a set of more or less manifest background assumptions and practices. Consider, for instance, the following five sentences: (a) *Jane opened the window*, (b) *Jane opened her book on page 56*, (c) *Jane opened the wall*, (d) *Jane opened her mouth*, (e) *The doctor opened her mouth*. Carston assumes that the encoded meaning of the English verb *open* does not vary in all five examples, although *open* receives quite different interpretations, depending on a set of background assumptions about different practices of opening. The Background is construed as a set of weakly manifest assumptions and practices in an individual's cognitive environment. Since the Background always supplies additional meaning to the interpretation of an utterance, the proposition expressed by an utterance cannot be fully determined by the meaning of its parts and the mode of their combination. Consequently, the principle of semantic compositionality does not hold for the proposition expressed, but only for the underdetermined logical form (i.e., the first step of interpretation).

As does Levinson (2000), Carston, too, argues that Grice does not account for the fact that 'what is said' is not independent from pragmatic input. However, Carston and Levinson differ in their approaches to the question of how the pragmatic intrusion problem needs to be dealt with. As shown above, Levinson develops a pragmatic subtheory of GCIs, dealing

only with the pragmatic processes involved in the elaboration of 'what is said'. By contrast, Carston favors a unitary account of all pragmatic processes, irrespective of whether they contribute to the 'what is said' or to different implicated assumptions (corresponding to Levinson's PCIs).

Carston's (2002: 377) use of the terms *explicature* and *implicature*, essentially based on Sperber and Wilson's (1995: 182) distinction between explicit and implicit assumptions/propositions, is spelled out in the following way (cf. Carston, 1988):

Explicature

An ostensibly communicated assumption that is inferentially developed from one of the incomplete conceptual representations (logical forms) encoded by the utterance.

Implicature

An ostensibly communicated assumption that is not an explicature; that is, a communicated assumption which is derived solely via processes of pragmatic inference.

The difference between explicatures and implicatures lies essentially in the way they are supplied: explicatures are developments of the logical form that they contain as a proper subpart, whereas implicatures are derived purely inferentially. In regard to these two kinds of pragmatic enrichment, the cognitive approach Carston promotes motivates the distinction between 'communicated assumptions' and the 'inferential steps' leading to them. Carston argues that explicatures are construed by means of interpretative hypotheses rather than by (generalized) implicatures.

Consider the example: *John came in and he sat down*. The preferred interpretation for the personal pronoun *he* in the second sentence is the coreferential one. Following Levinson, this interpretation results from an I-implicature. Carston argues that this implicature must be a proposition like '*He* refers to whomever *John* refers to', "a propositional form representing a hypothesis about reference assignment" (Carston, 2002: 151). She rejects the idea of reference assignment being an implicature and rather identifies it as an interpretative hypothesis like '*John* came in and he, *John*, sat down,' which is derived online and only confirmed if it meets the expectation of relevance. Carston claims that this strategy is able to resolve the dilemma of Grice's circle, for the simple reason that interpretation processes can be effected simultaneously.

Finally, the cognitive approach leads Carston to reject *conventional implicatures*; these are subsumed under the procedural elements. Relevance Theory distinguishes between concepts as constituents of mental representations, and procedures that constrain pragmatic inferences. Conventional implicatures conveyed by expressions such as *moreover* and

therefore do not contribute to the conceptual part of the utterance, but point the hearer to the kind of pragmatic processes she is supposed to perform (cf. Blakemore, 2002) (see **Meaning: Procedural and Conceptual**).

Bach (1994), who tries to defend the Gricean notion of 'what is said,' criticizes the notion of explicature and proposes instead the term *implicature* (cf. also Bach, 2001). Implicatures are either *expansions* of 'what is said,' as in *You are not going to die [from this little wound]* or *completions*, as in *Steel isn't strong enough [for what?]*. In these cases, "the resulting proposition is not identical to the proposition expressed explicitly, since part of it does not correspond to any elements of the uttered sentence"; hence Bach considers it "inaccurate to call the resulting proposition the explicit content of an utterance or an explicature" (Bach, 1994: 273).

Carston views Relevance Theory as a cognitive theory of utterance understanding that aims at the subpersonal level, where processes are fast and automatic. Thus, it should be clear that this theoretical goal differs from that pursued by Grice (cf. Saul, 2002). It must be noted, however, that arguments from psycholinguistic research are called for in order to constrain the theory.

First, it may be asked how children acquire implicatures and what roles maxims, principles, and the like play in this process. There are studies on the acquisition of irony and metaphor by Winner (1988) as well as studies on the role of Gricean principles in lexical acquisition (cf. Clark & E V, 1993, 2004). More recently, studies have been done on the acquisition of scalar implicatures, in particular dealing with the hypothesis that small children are "more logical" than older children and adults, in that they more readily accept the "some, perhaps all" – reading of the quantifier *some* (cf. Noveck, 2001; Papafragou and Musolino, 2003).

Second, there is some evidence that hearers do not first compute the literal meaning, then the nonliteral or indirect meaning, but that they arrive at the nonliteral/indirect meaning earlier or in a parallel fashion (cf. Shapiro and Murphy, 1993; Récanati, 1995; Gibbs, 2002; Giora, 2003). It is obvious that experimental research is very important for implicature and explicature theory (cf. Wilson and Sperber, 2004: 623–628).

Quality Reconsidered

In the development of neo-Gricean approaches to implicature such as Horn's and Levinson's, the Gricean maxim of Quality has been neglected. Thus, genuine pragmatic matters such as metaphor, irony,

sarcasm, lying, etc. have become largely unattractive for some implicature theorists, although metaphor had been featured as a cardinal case of maxim exploitation already early on (cf. Levinson, 1983: 147–162). Relevance Theory, on the other hand, which takes a stand on Grice as well as on neo-Gricean approaches, has developed an independent theory of irony; moreover, Carston (2002: Ch. 5), analyzes metaphors as instances of *ad hoc*-concept construction. In neither of these approaches, however, does the maxim of Quality play any role (see **Metaphor: Psychological Aspects**).

First, consider *irony*. If a speaker A utters *X is a fine friend*, referring to a person who has betrayed a secret of A's to a business rival, then the first maxim of Quality is flouted (Grice, 1989: 34). Because it is obvious that A does not believe what he says, the hearer reconstructs a related proposition, i.e., the opposite of p. The ironical implicature qualifies for the status of an implicature, because it is calculable, context-dependent, and cancellable. Note that this substitutional analysis is in contrast to the additive nature of other types of implicature. However, this approach has been criticized for several reasons: (i) The analysis cannot account for ironical questions, requests and understatements, (ii) it cannot explain the distinction between irony and metaphor, because the latter is also explained with regard to the first maxim of Quality, and (iii), it is not fine-grained enough, because it does not follow from 'He is not a fine friend' that he is not a friend at all.

The Gricean approach to irony has been most prominently attacked by relevance theorists (Sperber and Wilson, 1981; Wilson and Sperber, 1992; Sperber and Wilson, 1998). Following Sperber and Wilson, ironical utterances have four main properties: (i) They are mentioned, not used, (ii) they are **echoic** in nature, (iii) the ironical interpretation is an implicature that is derived through recognition of the echoic character of the utterance (Sperber and Wilson, 1981: 309), (iv) the ironical speaker displays a dissociative attitude towards the proposition uttered. Take the utterance *What lovely weather!* as an example. When uttered during a downpour, the speaker cannot mean the opposite, because this would be uninformative. Instead, he wants to convey that it was absurd to assume that the weather would be nice. Thus, the ironical utterance is a case of echoic mention of a previously entertained proposition. Types of echo include sarcastic repetition (31), attributed thoughts (32), norms (33) and standard expectations (34) (cf. Sperber and Wilson, 1998):

- (31) A: I'll be ready at five at the latest.
B: Sure, you'll be ready at five.

- (32) A: I'll be ready at five at the latest.
B: You mean at five tomorrow?
- (33) A: I'll be ready at five at the latest.
B: You are so punctual.
- (34) A: I'll be ready at five at the latest.
B: It's a great virtue to be on time!

Thus, the echo theory of irony does not imply that there is always an original utterance that is exactly reproduced. The echo theory is constrained in that most utterances cannot be interpreted as echoes, and echoic interpretations must contribute to the relevance of an utterance.

Several objections to this theory may be made (cf. Sperber and Wilson, 1998): (i) The notion of an echo is far too vague; it does not make sense to look for an echo in cases of conventional irony, e.g., when somebody utters *Boy, is it hot!* when it is icy cold. (ii) Because not every echoic mention is ironical, echoic mention is not sufficient to explain ironical interpretation. (iii) It is not clear why the substitution of the opposite should not be a starting point in the search for the dissociative attitude of the speaker towards the proposition. (iv) Relevance Theory cannot explain why hearers often fail to grasp the relevance of an ironical utterance.

Second, consider *metaphor*. For Carston (2002), metaphors are cases of *ad hoc* concept construction. *Ad hoc* concepts are those concepts “that are constructed pragmatically by a hearer in the process of utterance comprehension” (Carston, 2002: 322). Typical instances of *ad hoc* concepts come about via narrowing or broadening. *Narrowing* may be illustrated by utterances like *Ann is happy*, where the concept associated with *happy* in a particular context is much narrower than the encoded concept. The case of *broadening* is exemplified by utterances like *There is a rectangle of lawn at the back*, where it is very unlikely that the encoded concept of *rectangle* is communicated. Both processes are cases of constructing an *ad hoc* concept that contributes to the explicature.

If metaphors are *ad hoc* concepts, then they are part of the explicature as well. Thus, in *Mary is a bulldozer*, the logical form of *bulldozer* is associated with an *ad hoc* concept **BULLDOZER*** differing from the concept **BULLDOZER** usually encoded by this word. In this approach, metaphor isn't an implicature any more, as Grice (1989) and Levinson (1983) would have it, but an explicature.

Recall that for Horn (1984), the maxim of Quality was unreducible. Since then, its domain of application has considerably shrunk. However, it still seems to play a role when it comes to the analysis of lying, deception, insincerity, and – maybe – irony (cf. Wilson and Sperber, 2002; Meibauer, 2005). In Levinson's

(2000) approach, matters of irony, etc., are dealt with in the component called Gricean Pragmatics 2. Maybe it is there that the maxim of Quality will have a comeback. It is clear that some version of the maxim plays also a role in the definition of success conditions for assertive illocutions (see **Irony**).

Implicature and the Grammar/Pragmatics Interface

As has become clear from the sketch presented here of Levinson's and Carston's frameworks, pragmatic inferencing is powerful enough to influence semantic representations (see **Semantics–Pragmatics Boundary**). However, when it comes to pinpoint the exact relations of implicatures to illocutions on the one hand, and sentence types on the other, there still are many open questions.

First, consider implicatures *vis-à-vis* illocutions. Even if both are associated with an individual speech act, these notions refer to different entities: an additional proposition, in the case of implicature, vs. a type of act such as a promise, assertion, request etc., in the case of illocution.

An important connection between illocutions and implicatures is usually seen as obtaining in the case of *indirect speech acts* (see **Speech Acts**). According to Searle (1975), a reconstructive process that leads the hearer from the secondary illocutionary point (the 'literal' illocution) to the primary illocutionary point (the intended illocution) is similar to the scheme of reasoning that Grice proposed for conversational implicatures; step 2 of his sample derivation even includes principles of conversational cooperation (compare also the speech act schema proposed by Bach and Harnish, 1979). Accordingly, indirect speech acts have sometimes been analyzed as implicatures, for example the question *Can you close the window?*, meant as a request to close the window, a case that is related to the R-Principle as proposed by Horn (1989, 2004).

A case in point is the *rhetorical question*. Whereas Meibauer (1986) analyzes them as indirect speech acts, i.e., interrogative sentences types associated with assertive force and polar propositional content, Romero and Han (2004) analyze negative *yes/no* questions like *Doesn't John drink?* as connected with a positive epistemic implicature such as 'The speaker believes or at least expects that John drinks.' It is not clear at first sight whether such analyses are compatible; in any case, as Dascal (1994) has shown, the notions of implicature and speech act are independently motivated, and should not be confused. Thus, the question of their interrelation requires further research.

Second, consider implicatures vis-à-vis sentence types. It is widely accepted that there is a systematic connection between sentence types such as declarative, interrogative, and imperative, etc., and illocutions such as assertion, question, and request, etc.; moreover, in some approaches the existence of an intermediate category ‘sentence mood’ is assumed (cf. Sadock and Zwicky, 1985; Harnish, 1994; Reis, 1999; Sadock, 2004; Zanuttini and Portner, 2003). However, while it is conceivable that sentence types determine a certain illocutionary potential, the analogical notion of an ‘implicature potential’ has never been proposed, probably because of the authors’ concentration on lexical elements that give rise to GCIs.

However, there are several observations showing that such a concept is not totally mistaken. Consider the following examples:

- (35) Who is the professor of linguistics at
Tübingen? +> Someone is the professor of
linguistics at Tübingen.
- (36) [I gave the encyclopedia to Bettina.] You gave
the encyclopedia to WHOM?
- (37) Visit Markus and you’ll get new ideas! +> If
you visit Markus then you’ll get new ideas.
- (38a) This is good. +> This is not excellent.
(38b) Is this good? *+> Is this not excellent?

In (35), we have the case of an existential implicature that is typically bound to *wh*-interrogatives, but shows the properties of variability and cancellability. (Its classification as an existential presupposition, cf. Levinson, 1983: 184, has been abandoned, because it does not survive the negation test.) Example (36) illustrates the echo-*wh*-question. As Reis (1991) has persuasively argued on the basis of German data, these sentence types are neither ‘echo-*wh*-interrogatives’ nor *wh*-interrogatives. Instead, these utterances are regular instances of any sentence type, and their interrogative force is explained as a conversational implicature triggered by the *wh*-element (see also Reis, 1999). Another example showing that implicatures are sensitive to sentence types is the conditional imperative in (37) (cf. Davies, 1986; Clark, 1993). Finally, if elements that trigger scalar implicatures are in the scope of a question operator, the respective implicature may be blocked, as shown in (38) (the asterisk * denotes a blocked or unallowed implicature). In summary, then, there is evidence of a systematic interaction between implicatures and sentence types. The question is, then, how and where to account for this interaction.

A detailed analysis of the sentence type-implicature relation is developed in Portner and Zanuttini (2000).

They concentrate on negated *wh*-interrogatives and exclamatives in Paduan, a northern Italian dialect spoken in the city of Padua:

- (39a) Parcossa *no* ve-to anca ti!? (*wh*-interrogative)
Why NEG go-s.cl also you
‘Why aren’t you going as well!?’
- (39b) Cossa *no* ghe dise-lo! (*wh*-exclamative)
what NEG him say-s.cl
‘What things he’s telling him!’

The point is that the NEG-element has no negative force. In principle, there are two strategies for analyzing examples like (39): First, as a special type of negation, nonpropositional, expletive, or modal in character. The second strategy, as proposed in Meibauer (1990) on the basis of German data, is to assume regular negation, and to derive the modal effect from pragmatic principles. Portner and Zanuttini (2000), drawing on the latter approach, assume that exclamatives are factive. The negation particle *no* triggers a conventional implicature, which says that the lowest element from a set of alternative elements (that are possible in a contextually given scale) is true. In cases like (39a), there is an expectedness scale {less expected < more expected}, in cases like (39b), there is an unexpectedness scale {more expected < less expected}. The scales are dependent on the respective sentence type. While it is not clear (i) whether exclamatives constitute a separate sentence type at all (cf. d’Avis, 2001), (ii) why the implicatures are of the conventional type, and (iii) how the relevant scales are obtained from the context, it should be clear that such an approach paves the way for a more empirical research on the interplay of sentence types and implicatures.

Conclusions

On the basis of the foregoing sketch of three major approaches to implicature theory, we may state some of the prevailing tendencies. To begin with, there is a striving to understand implicatures in terms of economy. This is true for Levinson’s insight that implicatures help to overcome “the slowness of articulation,” as becomes clear from his slogan “inference is cheap, articulation expensive” (Levinson, 2000: 29), as well as for Horn’s appeal to the principle of least effort and Sperber and Wilson’s view on optimal relevance. Lately, recent developments in Optimality Theory have shown attempts to integrate the interplay of maxims into their frameworks.

Second, there is a tendency to reject the classic dual distinction between ‘what is said’ on the one hand, and ‘what is implicated’ on the other. Instead, a three-level approach to meaning is favored, cf. the distinction in Levinson (2000: 21–27) between

sentence meaning, utterance type meaning, and speaker meaning, or Carston's three-level model of utterance interpretation. However, there is considerable terminological confusion here, as the diagram in Levinson (2000: 195) impressively shows; confusion that has to do with the still unsolved problem of finding demarcation lines or fixing the interfaces between 'what is said' and 'what is meant.' Further discussion of the question of level architecture can be found in Récanati (2004).

Obviously, the second tendency is connected with the widely accepted view that some sort of underdeterminacy thesis is correct, and that there are presemantic pragmatic processes that are input for model-theoretic interpretation (cf. Levinson, 2000: 188), or are necessary to fix full propositional representations (cf. Carston, 2002).

As has become clear, there are still many problems to solve: the status of the maxims of Relevance and Manner, the distinction between GCI and PCI, the status of conventional implicatures, the interaction of implicatures with illocutions and sentence types, to name only a few. Besides, the role that implicatures play in many areas, such as those of language acquisition and language change, awaits much further research.

Indeterminacy, Semantic

M Hymers, Dalhousie University, Halifax, Nova Scotia, Canada

© 2006 Elsevier Ltd. All rights reserved.

Contemporary philosophy has presented two significant challenges to the determinacy of meaning, one contentiously associated with Ludwig Wittgenstein through the work of Saul Kripke (see **Rules and Rule-Following**) and the other, the topic of this entry, traceable to the behaviorism of W. V. Quine by way of his thought experiment concerning radical translation.

Quine purports to offer two distinct arguments for semantic indeterminacy, which he sees as a consequence of the thesis of the *indeterminacy of translation*: “manuals for translating one language into another can be set up in divergent ways, all compatible with the totality of speech dispositions, yet incompatible with one another” (1960: 27). This thesis has semantic implications for Quine, because as a behaviorist he holds that meaning is nothing above and beyond what is preserved in translation. This article will discuss both arguments for this thesis and reactions to them in separate sections below, focusing largely on the so-called argument ‘from below’ (1970: 183).

The Argument from Below

The radical translator, says Quine, is someone who has at her disposal only the behavior of the speaker of the alien tongue she is trying to translate and the observable objects and events that grace the locale she shares with the speaker. More carefully, Quine focuses not on those objects and events themselves, but on the stimulations they produce at the speaker’s nerve endings (see **Radical Interpretation, Translation and Interpretationalism**) and on the speaker’s observed disposition to assent to or dissent from sentences that the translator puts to her as queries under given *stimulus-conditions*. If she can formulate correct hypotheses about the speaker’s terms for affirmation and dissent, then this evidential constraint entails that the field linguist can translate *observation-sentences*, which are among the class of sentences to which assent is cued directly to particular occasions and to which, moreover, assent varies little or not at all with changes in the background information available to the speaker (1960: 42). The thought here is that reports of observations are reports of things observed on particular occasions (unlike talk of biological speciation or social justice), and those

things are importantly independent of the speaker’s background beliefs and mental states (unlike hallucinations, for example). Each such sentence has what Quine calls a *stimulus-meaning* – the ordered pair of its positive stimulus-conditions (those prompting assent to the sentence) and its negative stimulus-conditions (those prompting dissent from the sentence). Logical connectives such as ‘not,’ ‘and,’ ‘or,’ and ‘all’ can also be translated, because “one’s interlocutor’s silliness, beyond a certain point, is less likely than bad translation” (59). This ‘principle of charity’ (59n) has it that, for example, a speaker will not typically affirm both a sentence and its negation. We can, as well, identify but not necessarily translate sentences that are *stimulus synonymous* (those provoking assent and dissent respectively under exactly the same stimulus conditions) and sentences that are *stimulus analytic* – those to which the speaker will assent, if not to nothing, on every stimulus occasion (54–55).

Quine begins with sentences because a speaker assents to (or dissents from) utterances of sentences, not to (or from) isolated subsentential terms. But a thorough ‘translation manual’ should tell us how to match up individual words or other subsentential expressions (1960: 69). The radical translator may thus formulate a set of *analytical hypotheses* (68), which break down sentences into their component parts, words, which can then be found in other sentences. A survey of their occurrences in different sentences makes it possible to pair those words with words of the translator’s language, eventually yielding a comprehensive translation manual, whose adequacy can be further tested by recombining the isolated words into new sentences and observing the speaker’s pattern of assent and dissent to them. However, Quine contends, there will always be more than one overall system of analytical hypotheses that will yield workable translations, because local incompatibilities in competing hypotheses can always be compensated for by making changes elsewhere in the system. Thus, to take a trivial case, in the French ‘*ne...rien*,’ ‘*rien*’ can be translated either as ‘anything’ or as ‘nothing,’ says Quine, “by compensatorily taking ‘*ne*’ as negative or as vacuous” (1969a: 37).

Worse still, even if one’s analytical hypotheses isolate a particular word, the reference of that word may itself remain ‘behaviorally inscrutable’ (1969a: 35), for there is no empirical test that will decide between translations of the word ‘*gavagai*’ as ‘rabbit’ and as ‘undetached rabbit parts,’ given that apparent evidence against one translation can again be compensated for by making adjustments elsewhere in

the system (see **Holism, Semantic and Epistemic**). Inquiries whether this *gavagai* (rabbit) is the same as that *gavagai* (rabbit) may as easily be taken as inquiries whether this *gavagai* (rabbit part) belongs with that *gavagai* (rabbit part) (33). Beyond the level of observation-sentences and logical connectives, Quine contends, translation is radically indeterminate.

Quine assumes that overt bodily behavior is the only relevant evidence for the field linguist's efforts (1990: 37–38; see **Behaviorism: Varieties**), and he allows that the radical translator might have access to the totality of such evidence – that competing translation manuals might “accord perfectly . . . with all dispositions to behavior on the part of all the speakers concerned” (1969a: 29). Therefore, his conclusion is not merely that I cannot *know* what the unique, correct translation of the speaker's utterances is, but that there is *no fact* about what their unique, correct translation is, because all the relevant evidence leaves the question unanswered. Moreover, Quine holds that the same considerations apply to understanding a speaker of my own language – even when that speaker is myself. “On deeper reflection, radical translation begins at home” (46). This is because first as a learner of my own language and then as an interpreter of my colinguists, I have access to no more evidence than the radical translator does. It follows that meaning itself is radically indeterminate.

Reactions to the Argument from Below

Critics have complained that behaviorism is false and, so, that Quine's argument fails to establish its conclusion (Chomsky, 1969); and that Quine, in spite of his avowed behaviorism (Quine, 1990: 37), helps himself to nonbehaviorist data about the speaker's *nonobservational* terms for assent and dissent (Hockney, 1975: 421; Glock, 2003: 178) and about the communicative exchange between speaker and radical translator (Glock, 2003: 175–182). Assent and dissent cannot simply be read from the speaker's behavior, and they cannot intelligibly be assigned stimulus-meanings. The only way that the field linguist can identify terms of assent and dissent is by assuming that the speaker *wants* to be interpreted and understood, that the speaker *understands* that she is being interpreted, that the speaker is familiar with performing the *speech acts* of *answering* a question and *correcting* the linguist's proffered usage, and so on. These assumptions are all ruled out by Quine's behaviorism.

Critics have also doubted whether there really could be entire alternative translation manuals of the sort Quine envisions. The contention, very roughly, is that the compensatory changes that Quine imagines making to other terms in one's translation

manual in order to preserve one's favored translation of some given term would quickly come into conflict with the behavior of the speaker (Evans, 1975: 345–346). If I translate *gavagai* as ‘undetached rabbit part’ instead of as ‘rabbit,’ for example, I may have to translate the speaker as allowing that an undetached rabbit part is white if and only if the entire rabbit is white (Miller, 1998: 139). But this has consequences for how I should translate the speaker's word for ‘white’ in other contexts, and I should not be surprised to discover that I want to translate her as affirming that snow is white, even when visible patches of it have been visited by local sled dogs.

The Argument from Above

Quine might try to meet some of these objections by appealing to the argument ‘from above’ (1970: 183). Physical theory, says Quine, is underdetermined by the available evidence. More than one set of physical hypotheses could be compatible with the totality of empirical evidence. However, even if we select a particular physical theory on pragmatic grounds, Quine contends, our linguistic theory will remain underdetermined relative to our physical theory – “even if we ‘fix’ the physics” (Putnam, 1978: 53), nonobservational meaning will remain underdetermined. Linguistic hypotheses are underdetermined by a set of *more basic* ‘facts’ that are themselves already underdetermined. It is this double underdetermination that distinguishes semantic indeterminacy from normal empirical underdetermination.

Reactions to the Argument from Above

It is not clear, however, that this second argument operates independently of the argument from below, for the only plausible reason for thinking that the linguistic data are doubly underdetermined with respect to physical theory seems to be that mere physical behavior and the observation-sentences it undergirds are more evidentially basic – the only evidence we have to go on – and rival systems of analytical hypotheses are compatible with that evidence (Kirk, 1986: 140–146; Miller, 1998: 147). Moreover, as Chomsky complains, even if linguistics remains underdetermined once the physics has been fixed, it is equally true that the physics remains underdetermined once the linguistics has been fixed (Chomsky, 1980: 20; Rorty, 1972: 451–453). Only if we grant physics a special privilege could there be a problem for the determinacy of meaning.

Quine's work has, nonetheless, been very influential in analytical philosophy of language, leading especially to the varieties of *interpretationalism*

defended by Donald Davidson and Daniel Dennett (see **Radical Interpretation, Translation and Interpretationalism**).

Indexicality: Philosophical Aspects

E Corazza, University of Nottingham,
Nottingham, UK

In most of our linguistic interchanges and thinking episodes, we rely on context to select items of discourse and items of thought. One often succeeds in talking and thinking about something because one is situated in a given context. In natural language we have tools whose specific function is to exploit the context of use in order to select an item in one's surroundings. If one says, 'It is raining here' while in London, one refers to London because one's utterance occurs in London. Were one to utter the same sentence in Paris, one would be referring to Paris. We can use the very same words and yet refer to very different items. When you use 'I', for instance, you refer to yourself, whereas when I use it, I refer to myself. We use the very same linguistic expression with the same conventional meaning. It is a matter of who uses it that determines *who* the referent is. Moreover, when Ivan, pointing to Jane, says 'she' or 'you,' he refers to Jane; Jane, however, cannot refer to herself using 'she'

or 'you' (unless she is addressing an image of herself). If we change the context – the speaker, the time, the place – in which these expressions occur, we may end up with a different referent.

Among the expressions that may switch reference with a change in context, we have personal pronouns ('my', 'you', 'she', 'his', 'we'...), demonstrative pronouns ('this', 'that'), complex demonstratives ('this pencil', 'that brunette in the corner'...), adverbs ('today', 'yesterday', 'now', 'here'...), adjectives ('actual', 'present'), and possessive adjectives ('my pencil', 'their car'...).

These expressions have been termed, following Peirce, *indexicals*. Indexicals constitute the paradigm of context-sensitive expressions, i.e., those expressions that rely on the context of use to select an object of discourse. Reichenbach (Reichenbach, 1947) claimed that indexicals are *token reflexive*, for they can be defined in terms of the locution 'this token', where the latter (reflexively) self-refers to the very token used. So, 'I' can be defined in terms of 'the person who utters this token', 'now' in terms of 'the time at which this token is uttered', 'this pen' in terms of 'the pen indicated by a gesture

accompanying this token', etc. The reference of an indexical expression depends on its particular linguistic meaning: 'the utterer of this token' is the linguistic meaning (the *character* (Kaplan) or *role* (Perry)) of 'I', while 'the day in which this token is uttered' is the linguistic meaning of 'today', and so on. The meaning of an indexical can be viewed as a rule which one needs to master to use an indexical correctly. An indexical's linguistic meaning can be conceived as a function taking as its argument the context and giving as its value the referent/content (this is Kaplan's famous content/character distinction).

It is often the case, however, that the linguistic meaning of expressions such as 'this', 'that', 'she', etc., together with context, is not enough to select a referent. These expressions are often accompanied by a pointing gesture or demonstration, and the referent will be what the demonstration demonstrates. Kaplan (1977) distinguishes between *pure indexicals* ('I', 'now', 'today', ...) and *demonstratives* ('this', 'she', ...). The former, unlike the latter, do not need a demonstration – or *directing intention*, Kaplan (1989) – to secure the reference.

In their paradigmatic use, pure indexicals differ from demonstratives insofar as the latter, unlike the former, are perception based. When one says 'I', 'today', etc., one does not have to perceive herself or the relevant day to competently use and understand these expressions. To competently use and understand 'this', 'she', etc., one ought to perceive the referent or demonstratum. For this reason, when a pure indexical is involved, the context of reference fixing and the context of utterance cannot diverge: the reference of a pure indexical, unlike the reference of a demonstrative, cannot be fixed by a past perception.

Moreover, a demonstrative, unlike a pure indexical, can be a vacuous term. 'Today', 'I', etc., never miss the referent. Even if I do not know whether today is Monday or Tuesday and I am an amnesiac, when I say 'Today I am tired,' I refer to the relevant day and to myself. By contrast, if one says 'She is funny' while hallucinating, or 'This car is green' while pointing to a man, 'she' and 'this car' are vacuous.

In addition, pure indexicals cannot be coupled with sortal predicates, while 'this' and 'that' often are used to form complex demonstratives such as 'this *book*', 'that *water*'. Sortal predicates can be considered to be *universe narrowers* which, coupled with other contextual clues, help us to fix a reference. If one says 'This liquid is green' while pointing to a bottle, the sortal 'liquid' helps us to fix the liquid and not the bottle as the referent. Moreover, personal pronouns which work like demonstratives (e.g., 'she', 'he', 'we',) have a built-in or hidden sortal. 'She', unlike

'he', refers to a female, while 'we' usually refers to a plurality of people, of whom one will be the speaker.

Indexicals are generally conceived of as singular terms that contribute a referent to what is said. According to the *direct reference* view (from Kaplan and Perry), utterances containing indexicals express singular propositions, i.e., propositions whose constituents are the referents of the indexicals. As such, indexicals are usually characterized as expressions whose interpretation requires the identification of some element of the utterance context, as stipulated by their linguistic meaning. Thus, an utterance of 'I am tired' expresses a proposition containing the referent of the first person pronoun, and one understands it insofar as one knows to whom the term 'I' refers in the context in which it is uttered. The linguistic meaning governing the use of the indexical – such as 'the agent of the utterance' *qua* meaning of 'I', 'the day of the utterance' *qua* meaning of 'today' – does *not* feature as a constituent of the proposition expressed.

If indexical expressions are characterized as singular terms contributing their referents into what is said (i.e., the proposition expressed), adjectives such as 'local', 'distant', 'actual' – not to mention count nouns like '(a) foreigner', '(an) enemy', '(an) outsider', '(a) colleague' – would not fall into the same category, for they do not contribute a referent to the proposition expressed. Yet they are, plausibly, context-sensitive expressions. 'Local', 'foreign', and 'native' in 'A *local* bar is promoting *foreign* wine' and 'A *native* speaker should correct your essay' do not contribute a specific individual or individuals to the proposition expressed. Hence, they are not singular terms. It should be evident that context-sensitivity does not merely concern singular terms. It is worth distinguishing between indexicals *qua* singular terms, contributing their referents to the proposition expressed, and *contextuals qua* expressions which, though context-sensitive, are not singular terms. Adjectives such as 'tall', 'big', 'small', 'old', etc., also are context-sensitive, insofar as one is only tall/small/big/old ... relative to a comparison class. Jon may be too short to play tennis and yet too tall to be a jockey, while Jane may be too old to join the army and too young to take early retirement. But see Cappelen and Lepore (2004) and Borg (2004) for the view that words such as 'tall', 'foreigner', 'old', and the like are not genuinely context sensitive.

Proper names, like indexicals, also contribute individuals into the proposition expressed. As such they are singular terms, too; yet they are not indexicals (but see Recanati, 1993 for a different view). Nouns such as 'Monday', 'February', and the like also seem to contribute specific individuals in the proposition

expressed. They are best viewed in the same light as count nouns, i.e., as nouns such as 'lemon', 'frog', and 'table' (see Corazza, 2004). As such, they can be used to build singular terms. This happens when they are coupled with an indexical expression such as 'this', 'next', 'last' and they contribute to complex demonstratives of the form 'next week', 'last Saturday', 'next Christmas'. This peculiarity parallels the way count nouns can participate in building complex demonstratives such as 'these lemons', 'that table', 'this pen'. (King, however, defends the view that complex demonstratives are quantified terms).

One of the major features of indexicals differentiating them from other referential expressions (e.g., proper names: 'Plato', 'Paris'; mass terms: 'silver', 'water', terms for species: 'frog', 'raspberry', and so on) is that they are usually used to make reference *in praesentia*. That is, use of an indexical exploits the presence of the referent. Usually in a communicative episode involving an indexical, the referent is in the perceptual field of the speaker and contextual clues are used to raise the referent to salience (see Smith, 1989; Sidelle, 1991; and Predelli, 1998 for a discussion of indexicals used to refer to objects not present, e.g., answering machines, post-it notes, etc.)

When indexicals are not used to make reference *in praesentia* they exploit a previously fixed reference. 'That boy' in 'That boy we encountered yesterday was in trouble with the police' does not refer to someone present. In cases like this, the indexical makes reference *in absentia*. One can thus distinguish between the context of utterance and the context of reference fixing. In our example, the speaker and the hearer appeal to a past context to fix the reference. The gap between the two contexts would be bridged by memory. Another way to handle examples like this would be to argue that, in such cases, the indexical expression works like an anaphoric pronoun linked to a tacit initiator. In the sentence 'In 1834 Jane visited her parents, *now* two old, sick people,' 'now' does not refer to the time of the utterance. It refers to 1834. It does so because it is anaphorically linked to '1834', and, as such, it inherits its reference from it. A similar story could be told about 'that boy': it inherits its reference from a tacit initiator, i.e., an unpronounced NP which is nonetheless presupposed in the discourse situation. To stress this interpretation, consider the following exchange: Jane: 'It is raining'; Jon: 'Then I won't be there before tomorrow.' In saying 'It is raining,' Jane tacitly refers to the location she is in, say London. With 'there', Jon refers to the very same location and we can claim that he does so because 'there' works in an anaphoric way, inheriting its value from the tacit reference made by Jane.

Furthermore, indexicals differ from other referential expressions insofar as (in their paradigmatic use, at least) they cannot be deferential. While one often relies on the so-called division of linguistic labor when using non-indexical expressions (e.g., proper names or mass terms), one cannot depend on the same phenomenon when using an indexical. One can, for instance, competently use 'Feynman' or 'elm' even if one does not know who Feynman is and even if one is unable to tell an elm from a pine. Indeed, a blind person can utter 'that vase' when she has been told that there is a vase in front of her. In these uses the reference is fixed by someone else (it is deferentially fixed). However, these are far from being the paradigmatic uses of an indexical such as 'that/this'. In their paradigmatic uses, they refer to something the user is perceptually aware of. This difference between indexicals and other terms parallels the fact that when using proper names, mass terms, and the like, context is in play before the name is used. As Perry suggests, we often use context to disambiguate a mark or noise (e.g., 'bank', or 'Socrates' used either as a tag for the philosopher or for the Brazilian football player). These are pre-semantic uses of context. With indexicals, though, context is used semantically. It remains relevant after the language, words, and meaning all are known; the meaning directs us to certain aspects of context. This distinction reflects the fact that proper names, mass terms, etc., unlike indexicals, contribute to building context-free (eternal) sentences, that is, sentences that are true or false independently of the context in which they are used.

To sum up, philosophers have made several key claims about indexicals. They are tools whose function is to exploit context, and their hallmarks include not having a fixed referent, not being easily deployed *in absentia* of the thing referred to, not being used deferentially, and having context play (not just a pre-semantic role, i.e., determining which word has been used, but also) a semantic role. Philosophers have found that indexicals come in at least three varieties: pure indexicals ('I', 'now'), demonstratives ('this', 'she'), and contextuais ('foreign', 'local'). Key differences between the first and second variety are that, in contrast to pure indexicals, demonstratives are more perception-based, they may be vacuous, they can be combined with sortals, and directing intentions play a quite central role in their use. In addition to attracting the attention of philosophers, indexicals have also captured the interest of those working within the boundaries of cognitive science for several reasons (see, for instance, Pylyshyn, 2003 on how indexicality is relevant to the study of vision): they play crucial

roles when dealing with such puzzling notions as the nature of the self (see for instance the importance of 'I' in Descartes' cogito argument), the nature of perception, the nature of time, psychological pathologies, social interaction, and psychological development (see Corazza, 2004).

Innate Ideas

E Margolis, Rice University, Houston, TX, USA

S Laurence, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

The question of whether there are any innate ideas or concepts goes back to ancient times and is at the center of the dispute between empiricists and nativists. Empiricists maintain that the mind has little innate structure and that all of our concepts are based on perception. In contrast, nativists maintain that the mind has a great deal of innate structure, including a stock of innate concepts of considerable abstraction (e.g., CAUSE, AGENT, NUMBER).

The traditional dispute between empiricists and nativists, especially in the 17th and 18th centuries, often confounded psychological issues with epistemological ones. While the former address how the mind is organized and how it develops, the latter address the grounds for justifying our beliefs. Contemporary theorists view the psychological issues as being largely independent of the epistemological issues. Contemporary theorists also draw upon empirical studies of the mind to support their claims. The cognitive sciences – from linguistics to developmental psychology to cognitive anthropology – all bear on the innateness controversy. At the same time, questions about innate concepts continue to be hotly debated

among philosophers. One issue concerns what it means to say that a concept is innate and whether the notion of innateness has explanatory value. A second and related issue concerns which concepts (if any) are innate and how arguments for innate concepts are to be evaluated.

What Is Innateness?

Empiricists and nativists disagree about the innate structure of the mind. The disagreement is sometimes mischaracterized by saying that nativism is the view that the mind has an innate structure. This is a mistake, because the point of contention isn't about whether or not something is innate but is about how rich our innate endowment is. Even the most diehard empiricists maintain that the mind has an innate structure that is partly responsible for why humans develop the concepts they do. Even the behaviorist, as W. V. O. Quine notes, "is knowingly and cheerfully up to his neck in innate mechanisms" (1969, pp. 95–96). What distinguishes empiricists from nativists is that empiricists think that there are no innate concepts and that the innate mechanisms that explain how we acquire our concepts are general-purpose mechanisms (for empiricists the same mechanisms, ultimately based on our perceptual systems, are responsible for the development of such diverse concepts as NUMBER, BELIEF, SQUIRREL, and AXE). In contrast, nativists embrace innate concepts and allow that the mind may have considerable innate differentiation.

Some theorists are skeptical of the dispute between empiricists and nativists because they think that little sense can be made of the idea that anything is innate. This poses a potential challenge (to both nativists and empiricists) to clarify the notion of innateness.

One proposal is that innate concepts are ones that are genetically determined. Unfortunately, the notion of genetic determination is itself problematic. Every phenotypic trait is dependent upon both genetic and environmental factors (including the embryonic environment); none can be traced to the genes uniquely. In addition, the appeal to genetic determination relies on a misleading picture that a genotype is a blueprint specifying a detailed sketch of an organism's phenotypic properties. But according to modern genetics, the relationship between genes and phenotypes is far more indirect (Sterelny and Griffiths, 1999; Marcus, 2004).

Another proposal is that innate concepts involve a greater influence of the genes than the environment in the sense that innate concepts are bound to emerge in a wide range of environments (Sober, 1998). A related proposal is that a concept is innate to the extent that

its development is canalized; that is, there is a developmental process that is bound to form the concept regardless of environmental variation (Ariew, 1996). One problem with these sorts of approaches is that some concepts are likely to emerge across a wide range of environments not because they are innate but simply because they are readily *learned* in a wide range of environments. A second problem is that for an account of this kind to work we must be given a principled specification of the relevant environmental variation (Cowie, 1999; Samuels, 2002).

Another approach is to explain innateness in terms of the kind of explanation that accounts for a concept. Samuels (2002) suggests that a psychological structure is innate when it is posited by a correct psychological theory and yet there isn't a psychological account of how it is acquired. For example, a concept is innate if we must turn to a neurobiological explanation of its acquisition. Of course, this leads to the problem of clarifying what counts as a psychological (as opposed to a nonpsychological) explanation, but perhaps this distinction is well enough understood in practice.

Which Concepts are Innate?

Much of the contemporary discussion about which concepts are innate has centered around Jerry Fodor's notorious claim that all **lexical concepts** are innate. Roughly, lexical concepts are ones that are encoded by single words in natural language, as opposed to phrases – for example, the concept DOG is a lexical concept.

Fodor's original presentation of his argument has the feel of a paradox (Fodor, 1975). The argument begins with the distinction between learning and other fortuitous ways of acquiring a concept (e.g., bumping your head in just the right way or undergoing futuristic neurosurgery). Fodor claimed that learning, in contrast with these other ways of acquiring a concept, should be understood as a rational process in which hypotheses are tested. The problem, as Fodor saw it, is that hypothesis testing requires that one already have the concept one is attempting to learn. He points out that in so-called concept learning experiments, subjects are required to sort stimuli in accordance with a novel concept. But if the correct hypothesis is, for example, that the concept in question is the concept of something that is blue or square, then one would have to have prior possession the concept BLUE OR SQUARE – the concept that is supposed to be learned – in order to even be in a position to frame and test the hypothesis. In later work, Fodor refined his argument by allowing that

learning in some sense can take place so long as the acquired concept is complex. Learning is understood to be a process in which a new concept is constructed from previously available constituents in the course of framing and testing a hypothesis (Fodor, 1981). The problem now, however, is that the evidence is supposed to suggest that lexical concepts aren't complex, that they are actually atomic or primitive concepts (*see Concepts*). Fodor concluded that lexical concepts can't be learned, and hence that they must be innate.

The logic of Fodor's argument has been endorsed by such prominent cognitive scientists as Ray Jackendoff and Steven Pinker, who have agreed that concept learning can only be a process where complex concepts are assembled from their constituents (Jackendoff, 1989; Levin and Pinker, 1991). Where they have disagreed with Fodor is about the evidence regarding conceptual structure, maintaining that lexical concepts do in fact have the structure that would allow them to be learned. In contrast, philosophers have often simply dismissed Fodor's argument on the grounds that his strong form of nativism is inconsistent with evolution (Putnam, 1988). They point out that natural selection couldn't have given us an innate conceptual system that incorporates concepts of no utility to our ancestors (e.g., PROTON and SAXOPHONE).

Both of these reactions are unsatisfactory. The appeal to evolution barely addresses Fodor's argument. Simply dismissing his conclusion tells us nothing about where the argument goes wrong and gives us no insight whatsoever into how concepts can be learned. The strategy of localizing the disagreement to one about conceptual structure is certainly better. But it still embraces Fodor's fundamental assumption that there is no way of expanding the combinatorial expressive power of the conceptual system.

Another approach to Fodor's argument embraces the challenge of showing how a primitive concept can be learned (Margolis, 1998; Laurence and Margolis, 2002). The way to do this is to frame the issue of learning side by side with a theory of content that is suitable for primitive concepts, e.g., a causal theory of content. Roughly, on a causal theory of content, a concept's content is fixed by its standing in a nomic-causal relation with the property it expresses. These nomic relations aren't basic laws, so they must be supported by mechanisms that sustain the link between a concept and its corresponding property – sustaining mechanisms. Typical sustaining mechanisms involve inferential dispositions, but because of the assumption of conceptual atomism, different people (and the same person at different times) can have different sustaining mechanisms for the same

concept. What matters for the possession of a primitive concept is the property it is nomically connected to, not the mechanism that establishes the connection. The question of how a concept is acquired then becomes the question of how these sustaining mechanisms are established.

For natural kind concepts, one important type of sustaining mechanism may combine an appreciation of the typical appearance of a kind with a general disposition towards psychological essentialism (the view that instances of a natural kind have a common set of properties that bind them together and that account for the kind's appearance but are themselves not readily observable; see Gelman, 2003). If this is right, then acquiring a natural kind concept can be explained roughly as follows. Certain cues suggest that an object is an instance of natural kind; one is then disposed to keep track of its salient physical characteristics; and this information is organized around a new representation to interact with the general essentialist disposition. The result is a representation that is elicited by things with a similar appearance but that is withheld in those cases where the evidence suggests that the essential properties are missing.

It's natural to describe this whole process as one where a concept is learned, so it illustrates how a primitive concept *can* be learned. However, it doesn't follow that empiricism has been vindicated. Concept learning along these lines may depend upon innate cognitive mechanisms of considerable richness. For example, the model presupposes a disposition towards psychological essentialism and an ability to track natural kinds. These may very well be innate.

Moreover, nativist research has been flourishing in recent years with its focus on areas of cognition that are thought to be subserved by domain-specific systems. These are cases of distinct cognitive mechanisms that are differentiated in their developmental trajectory, that employ specialized computational operations, that draw upon a distinctive body of information, and that may be associated with specialized neural circuits. Some suggestions along these lines are a domain for reasoning about minds, a domain for reasoning about physical objects, a domain for reasoning about biological phenomena, and a domain for reasoning about social exchanges (Hirschfeld and Gelman, 1994; Carruthers *et al.*, 2005). Connected with these domains are strong candidates for innate concepts, including BELIEF, PHYSICAL OBJECT, ANIMAL, and CHEATER.

Innate Knowledge

T Simpson, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Debates over the existence and nature of innate knowledge have a long and complex history, in both philosophy and psychology in general and in language and linguistics in particular (see, e.g., Stich, 1975). As one might expect, such debates have produced many distinct and competing notions of innate knowledge and have also resulted in much disagreement over the existence of either necessary or contingent connections between any particular proposals (see, e.g., Griffiths, 2002). However, there are two senses of innate knowledge that consistently dominate both classical and contemporary work. First, that some set of 'ideas' or 'justified true beliefs' are present at birth, and, second, that there exists some set of domain-specific psychological mechanisms, capacities, faculties, or representations which are in some to-be-specified way biologically or genetically pre-determined.

Defense of innate knowledge in the first sense arguably began with Plato, who claimed that as we can be shown to possess 'genuine knowledge' for which experience is insufficient, then such knowledge must ultimately be something 'recollected' from what

we already know. Philosophers of the Enlightenment also considered in detail the question of what kinds of knowledge may be innate, and in so doing questioned what the very notion of innate might mean. In direct contrast to Plato, John Locke (1690) argued that there are, in fact, "no innate principles in the mind" because, among other things, no useful meaning can be given to the notion of innate. Locke argued that if there were any innate principles, then either these principles must be present in our minds from birth, or there must be some 'mark' by which we can distinguish in adult minds those principles which are innate from those acquired by experience. But, Locke claimed, any supposedly innate principles are clearly not present in the minds of infants and 'idiots,' nor can the required marks be found. Thus, Locke concluded, no useful meaning can be given to the notion of innate in the context of explanations of the origins and development of human knowledge.

Note, however, that Locke's arguments here speak only to an understanding of innate knowledge in the first sense given above. Thus even if such arguments are correct, it remains entirely possible that there exists innate knowledge in the second specified sense. Moreover, there are now sound theoretical and empirical reasons to believe that innate knowledge in this second sense does actually exist (see Carruthers

et al., 2005, for a more detailed discussion of what follows).

Physiological traits such as teeth or pubic hair can be usefully understood as innate in this second sense, and there seems no reason to think that some psychological traits could not be similarly so understood. Furthermore, since the middle of the 20th century, results from research in linguistics and other areas of cognitive science, inspired by the pioneering work of Noam Chomsky (1965, 1967) appear to show that there exist various specific psychological traits which necessarily cannot be acquired via individual experience – as well as other traits which perhaps could be so acquired but which demonstrably are not. Thus there do indeed appear to exist some psychological traits that bear a ‘mark’ that distinguishes them from those that are experientially acquired. So much so, in fact, that for many core cognitive domains (e.g., language, naive physics, and number) virtually all contemporary researchers and theorists accept that there exists some degree of domain-specific innate knowledge – in the second sense – relevant to the domain in question. As Chomsky notes, all contemporary linguists agree that “the question is not whether innate structure is a prerequisite for learning, but rather what it is” (1980: 310), and it is with regard to the specific details of this innate structure that debate between linguistic nativists and non-nativists now occurs.

Evidence for an innate language faculty comes from a wide variety of theoretical and empirical sources, most of which are driven by what have been termed ‘arguments from the poverty of the stimulus’ (see, e.g., Chomsky, 1967, 1981; Laurence and Margolis, 2001; Pinker, 1994). These arguments claim to show, through a variety of different means, that the linguistic competence acquired by normally developing children cannot be – or demonstrably is not being – acquired using predominantly empiricist or general-purpose learning methods and mechanisms. Rather, nativists claim, these arguments show that there must exist a considerable amount of innate knowledge which enables children to bridge the ‘gap’ between the language-related input they receive, and their resultant linguistic abilities. Indeed, when one considers the way in which research in linguistics has proceeded in recent years, it rapidly becomes clear just how large this gap is, and thus just how much innate linguistic knowledge children must actually possess in order to bridge it. Contemporary linguists have discovered a huge number of subtle, but nonetheless fundamental, regularities in our linguistic behavior and have put forward many different theories concerning the structure of language. Moreover, linguists have yet to comprehensively determine

the grammar of even a single human language. This alone suggests that children’s linguistic input is too impoverished to provide them with data sufficient to reach the one correct grammatical hypothesis, which they nonetheless reliably reach by the age of six years old.

In addition, there are theoretical decisions which the developing child needs to make – and reliably makes – but with which linguists have struggled for some considerable time. For example, are rules construction-specific or is sentence structure dictated by the interaction of a number of non-construction-specific rules? Are rules optional or mandatory? Do rules apply in a fixed order, or are they unordered? And so on. There is in fact a theoretically enormous range of grammatical hypotheses that the child could consider during language acquisition, but all normal children nonetheless always arrive at exactly the right hypothesis at approximately the same age. Moreover, all normal children also arrive at exactly the right hypothesis via pretty much the same route. If children were largely empiricist learners, one would expect that each child would try out a huge number of different grammars during language development, and also that the types of mistakes children would make would be highly variable. However, the sorts of errors children make are in fact highly circumscribed (Pinker, 1994; Crain and Pietroski, 2001). This (and much other) evidence therefore overwhelmingly supports the claim that there exists some degree of innate linguistic knowledge. The greater the amount and complexity of such innate knowledge one believes there is, the more nativist one is about our language abilities.

With regard to the actual content of our innate knowledge, many theorists (in linguistics and elsewhere) first draw a distinction between the information that cognition in any given domain requires, and the computational processes which operate on this information in that domain. More specifically, theorists often refer to representational modules and computational modules respectively (see, e.g., Fodor, 1983, 2000; Pinker, 1997; Samuels, 2000). The issue of what makes a cognitive capacity or faculty modular is complex and somewhat controversial (*see Modularity*), but to a first approximation, representational modules are domain-specific bodies of data (where this data is organized and integrated in the right kind of way), and computational modules are domain-specific processing devices. Thus, for instance, “a parser might be conceived of as a computational module that deploys the contents of a [representational] module devoted to linguistic information in order to generate syntactic and semantic representations of physical sentence

forms” (Samuels, 2000: 19). Similar distinctions and consequent models can be generated in various other cognitive domains. Once these distinctions are made, however, it becomes clear that some components of either or both kinds of module could be innate in any given domain, and thus that specifying the details of our innate endowment will require considerable care. In addition, as our innate linguistic endowment will involve at least some extremely specialized representations and computations specific to human grammar, there is no reason to expect there to be any direct isomorphism between the details of our innate linguistic endowment and those of our innate endowment in other cognitive domains. Claims about the details of the innate knowledge appropriate to any given cognitive domain must therefore ultimately be made only in the light of the appropriate domain-specific investigation.

Furthermore, while it is clearly the case that not all language-specific representations or computational processes are innate (i.e., children clearly determine which representations and processes they should actually use on the basis of the input from their local environment), there is also no reason to believe that all the innate components required for language acquisition are language-specific. That is, successful language acquisition may also require the operation of innately specified but more domain-general processes, such as ‘statistical samplers,’ which can or do operate on any auditory or other input. However, the need for such domain-general processes does not detract from the claim that some innate language-specific components also exist. The linguistic capacities children acquire, and the routes by which these capacities are reached, admit of no other explanation.

This is not to say that linguistic nativists are all agreed on the details of our innate language-specific components. Mark Baker (2005), for example, points out that while it is clear that something like the Head Directionality Principle exists as part of our innate linguistic endowment, it is not yet clear whether this principle is innately specified as:

1. Combine a word with a phrase to make a larger phrase by putting the new word first *or* by putting the new word last.

Or as:

2. Form a new phrase by adding a word to a phrase.

More generally, there is still much disagreement between linguistic nativists over whether our innate linguistic endowment is overspecified (as in 1) or underspecified (as in 2). Chomsky and many linguists who follow him currently argue broadly in favor of

the former, whereas Steven Pinker, most ‘functional’ linguists, and most developmental psychologists argued broadly for the latter. Resolution of this debate will ultimately be an empirical matter, of course, but current theoretical arguments do not tell decisively either way. Nor is it clear how similar issues in other cognitive domains should either influence or be influenced by results from language acquisition. Thus despite the overwhelming nature of the theoretical arguments and empirical data outlined in the previous paragraphs in favor of linguistic (and other) nativism, there still exist some significant – though healthy – disagreements between even the most canonical nativists over exactly what the details of our innate endowment are. Nonetheless, such disagreements should not obscure the fact that, in the linguistic domain and elsewhere, our innate endowment is undeniably both rich and complex.

Finally, there is also the question of how our (neuro-)biology is able to implement or otherwise provide the innate knowledge which our linguistic and other cognitive abilities require. Given that aspects of our linguistic competence are not the product of our linguistic experience, it seems that these aspects must therefore be part of our biological endowment. This may strike one as somewhat counter-intuitive, but as Stephen Crain, Andrea Gualmini, and Paul Pietroski (2005) have recently argued “[o]ne cannot insist that our shared biology cannot give rise to knowledge of specific contingent linguistic facts if the available evidence suggests that our shared biology does just this.” Moreover, it may turn out that the nature of these innate linguistic facts actually provides us with useful information about the manner in which human biology has evolved, given the evolutionary pressures and constraints which (proto-)language use will have imposed upon the primate lineage. Indeed, investigation into the interplay between our innate linguistic knowledge and the evolution of our species-typical biology, will undoubtedly be one of the more complex and fruitful areas for future research. The same is also likely to be true with regard our investigation into and our understanding of the innate knowledge involved in other cognitive domains.

In sum, then, in one important sense of ‘innate knowledge’ the existence of such knowledge in the context of linguistic and various other cognitive capacities is no longer in any serious doubt. However, much work is still required before our understanding of the specific nature of this knowledge will be complete.

Intention and Semantics

S Barker, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

A compelling idea is that words have meanings because speakers who use them have intentions of some kind. Intentions underpin semantics. One proposal of how this might work is based on Locke's idea (1975) that the function of a language is to express preexisting thoughts; thoughts are correlated with sentences through intentions. So intentions are the glue binding thoughts to words.

Grice (1958, 1969) adopts this Lockean view. Grice divides verbal meaning into two kinds: so called 'speaker-meaning' and 'sentence-meaning.' Speaker-meanings are the contents of particular utterances on occasions. They are the contents of illocutionary acts (in the sense of Austin, 1962) performed by production of sentences. Illocutionary acts include assertions, orders, questions, etc. Speaker-meanings may diverge from sentence-meanings, which are literal meanings. U may employ 'The church is a rock' but convey as speaker-meaning that the church is a strong support for its members; U may utter 'The meal is

edible,' conveying as speaker-meaning that it is not very good.

Grice begins his analysis of meaning by examining the intentions underpinning speaker-meaning. Grice takes the intentions that do the job to be communicative intentions. A communicative intention is social: it is directed toward an audience. In communication – speaking-meaning something – a subject *U* intends that her audience *H* gain a certain state *r*, a belief, desire, intention, etc. Grice's great insight was into the structure of the communicative intention, which he characterized thus:

C: *U* means something by utterance *S* if and only if *U* utters *S* and intends that *H* acquire characteristic *r* and *U* intends that *H* do so partly by recognizing this very intention.

The intention is a **reflexive intention**: an intention that falls within its own scope. Many philosophers have been wary of the reflexive treatment of communication and have attempted to explicate communicative intentions in terms of hierarchies of intentions. See Grice (1969), Strawson (1964), and Schiffer (1972). But the results are unwieldy.

Speaker-meanings are, then, acts with the form C. The different types of speaker-meanings or illocutionary acts, that is, assertions and orders etc., are determined by the different characteristics *r* intended. Grice (1971: 123) analyzes assertions and orders thus:

GA: *U* asserts (to *H*) that *P* by uttering *S* iff *U* utters *S* reflexively intending that *H* believe that *U* believes that *P*.

GO: *U* orders (*H*) to do *F* by uttering *S* iff *U* utters *S* reflexively intending that *H* form an intention to *F*.

Such proposals about *r* are problematic, however. Restricting ourselves to assertion, GA is refuted by apparent cases in which *U* lacks an intention that *H* believe that *P* – e.g., where *U* either (*a*) is indifferent as to *H*'s belief, because, for example, *U* is engaged in polite conversation without intending to persuade; or (*b*) believes *H* won't believe her. (See Alston, 2000). Bach and Harnish (1979), suggest the primary intention should rather be:

that *H* has a reason to believe that *U* believes that *P*.

If, as suggests Recanati (1986), reasons are defeasible, then *U* can provide a reason for *H* to believe *P*, even though *U* knows it is undermined by further information, such as that *H* believes *U* is a liar.

Assuming that some such explication of *r* works, how can we use speaker-meaning to analyze sentence-meaning? Grice (1971) introduces practices and conventions thus:

SM1: *S* means that *P* for *U* iff *U* has the practice that if she desires to reflexively intend that *H* gain *r*, then she (may) utter *S*.

The 'may' here can be taken as rule permissibility or epistemic 'may.' SM1 allows words to be ambiguous, and for there to be different ways of saying the same thing. Grice notes that the regularity governing use of the sentence *S* does not itself have to be one that correlates use of *S* with full-fledged reflexive intentions. Rather we simply need:

SM2: *S* means that *P* for *U* iff *U* has the practice that if she desires to intend that *H* gain *r*, then she (may) utter *S*.

If the conventions/practices governing sentences have this form, we can then explain how speaker-meanings – full illocutionary acts – emerge in particular utterance events. In uttering *S*, *U* intends *H* to think thus:

U's policy is that if *U* intends that *H* have *r*, then *U* (may) utter *S*.

U uttered *S*, so (given context) I can infer that *U* intends that *H* have *r*.

U intends that *H* have *r*.

So, I should have *r*.

Thus, *U* is intending that *H* have *r*, partly in virtue of recognizing *U*'s intention that she have *r*. But this is just reflexively intending that *H* have *r*.

To analyze word-meaning we need regularities such as:

WM: The word Ω means *O* for *U* iff *U* has the practice that if *U* desires that *H* believe *U* believes something about *O*, then *U* (may) utter a sentence ... Ω ...

Given that *U* has such dispositions for the basic vocabulary of her language, we can deduce the kinds of dispositions that will underpin her production of novel (unuttered) sentences. We provide thereby a compositional account of the meaning of sentences in *U*'s language.

Platts (1979: 86–94) doubts this last point. He thinks the very thing we are meant to be explicating, sentence-meaning, will have to be brought in to fix the intentions that *U* would have if she were to use novel sentences. Blackburn (1984: 127–129) objects that it is just the practices and dispositions themselves that fix what we would intend, and thus mean. Nothing else need back up such dispositions.

A more serious objection to the Gricean account of meaning is that repertoire rules for the words require us to appeal to the semantic relation of **aboutness**. WM invokes *U*'s believing something **about** object *O*. Aboutness is related to denotation, that is, a representational relation between mental state or word

and world. But meanings, one might think, are simply representations. So, as Devitt and Sterelny (1999: 150–151) point out, the Gricean analysis effectively leaves unexplained the realm of content as such. Perhaps we need a Fodorean (1975) language of thought hypothesis to finish the story. Or perhaps there is some way of giving a pragmatic reduction of representation in terms of an inferential semantics (Brandom, 1994). Or we should see Grice's analysis of speaker-meaning and its relation to sentence-meaning as merely providing an explanation of what it is for particular speakers to use one language – whose representational contents are abstractly defined in terms of truth-conditions – rather than another (Lewis, 1975). If so, as Blackburn (1984: 134) points out, there is no rivalry between intention-based semantics and formal truth-conditional approaches, *contra* Strawson (1964).

Or there is this possibility. An intention-based semantics might change tack by denying that meanings, *qua* semantic interpretations, are representations as such. This approach is found in Barker (2004). It contends that the semantic interpretations of words and sentences are not representational contents but speech act types – acts whose nature is not merely representational. These speech acts are a specific kind called 'proto-speech-acts.' A proto-act is uttering a word, phrase, or sentence and **advertising** certain intentions to denote, represent, or communicate. Advertising is engaging in the behavior characteristic of a speaker who, following certain rules, intends to do something. In uttering a name, for example *Pegasus*, U utters a term, *Pegasus*, and advertises an intention to denote an object, something called *Pegasus*. If U utters 'I saw Pegasus,' she wants H to believe she has the intention she advertises, but if she asserts 'Pegasus does not exist,' she does not. What defines a name's meaning is not any object denoted, since like *Pegasus* it might be empty, but the proto-referring act associated with it. The meaning of *Pegasus* is that proto-referring act all of whose tokens are nodes of a certain referential tree: that subset of uses of the name *Pegasus* that we group together as instances of the name for the mythical flying horse.

The meaning of a declarative sentence is a 'proto-assertion.' A proto-assertion involves two parts: advertising (a) a representational intention and (b) a communicative intention. In uttering 'Snow is white,' U advertises intentions (a) to represent that snow is white, and (b) to **defend** the intention to represent snow's whiteness. Defending is dialectical engagement with an audience H: in defending an intention to represent that snow is white, one wants H to accept or reject such an intention in her own

case, and to give reasons for rejection. H judges correct an **assertion** of 'Snow is white' – where U really does intend to defend an intention to represent that snow is white – iff H accepts what U defends.

Assertion of 'Snow is white' is a **report**, since what is defended is a representational intention. But not all assertions are reports. Utterance of 'Haggis is tasty' is an expression of taste: U advertises intentions to (a) represent her possession of a gustatory preference state of liking haggis, and to (b) defend that gustatory preference state. Preference states are not representational. H judges correct U's assertion iff H accepts the gustatory preference state in her own case; not if and only if H thinks U has represented correctly her, U's, state.

In this framework, all logically complex sentences have expressive proto-assertions as their meanings. Negations express rejective states. In uttering 'Snow is not white,' U advertises intentions to (a) represent that she has a rejective state with respect to intending to represent snow is white, and to (b) defend that rejective state. In uttering 'Haggis is not tasty,' U expresses rejection of the gustatory property. And so on for other logically complex sentences. Statements of the form 'S is true' are expressive as well; U expresses her acceptance of the state defended in assertion of S. Because sentence-meanings are not representations, we are not committed to logically complex entities in the world, such as negative or universal facts, or mysterious properties of truth.

A compositional semantics can be built through constructing meanings in terms of proto-acts, proto-referrings, and proto-assertions. Proto-assertions, for example, can embed in logical compounds. In 'either S or R,' S and R are proto-asserted. Hence **advertising** intentions is weaker than the condition articulated above of giving a defeasible reason to believe.

This approach does not attempt to explicate representation in speech act terms. Rather, it displaces representation as the keystone of meaning. Names and sentences don't have to denote/represent to be meaningful. Truth-bearers are not propositions, *qua* representational contents, but assertions: acts of defending states. This account does not tell us what denotation and representation are, but, unlike the Gricean approach, it is not committed to saying that meaning resides in such relations holding. The result is an intention-based semantics that seriously challenges the dominant truth-conditional approach to meaning.

Interpreted Logical Forms

M Montague, University of California, Irvine, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Interpreted logical forms (ILFs) were originally introduced by Harman (1972) to answer the question: What are the objects of propositional attitudes (belief, desire, hope, regret, etc.)? The theory has since been developed by a number of philosophers, most notably Higginbotham (1986, 1991), Segal (1989), Larson and Ludlow (1997), and Larson and Segal (1995). Seymour (1996) has suggested that ILF theories can also solve certain puzzles in quotational environments.

Propositional Attitude Reports

Consider the following two propositional attitudes:

- (1) Lois believes that Superman can fly.
- (2) Lois believes that Clark Kent can fly.

It is an 'intentional fact' that Lois may have the attitude displayed in (1) without having the attitude displayed in (2). It is a 'semantic fact' that sentences reporting these propositional attitudes may differ in truth value. Are these facts the same? No: one is a fact about intentionality, and the other is a fact about semantics. Is this difference important? According to the theory of ILFs advanced by Ludlow, Larson, and Segal, it is. Giving a semantics for

propositional-attitude reports, which is the goal of the ILF theories, has virtually nothing to say about propositional attitudes themselves: "The ILF theory ... (as a semantic theory) ... addresses only the truth conditions of sentences involving *believe*, *think*, *assert*, etc., it does not address the beliefs, thoughts, and assertions of persons" (Larson and Ludlow, 1997: 1035). By contrast, the ILF theory proposed by Higginbotham (1986, 1991) countenances a closer relationship between the theory of propositional attitudes and the semantics of attitude reports.

Since Frege (1892), a huge amount of attention has been given to the aforementioned semantic fact, which has become known as 'Frege's Puzzle.' Frege discovered that if 'Superman' and 'Clark Kent' refer to their ordinary referents in (1) and (2), according to the principle of substitution, that co-referring expressions may be substituted *salva veritate*, (1) and (2) should share a truth value. Since they intuitively do not, the principle of substitution seems to fail in propositional-attitude contexts. Frege's puzzle has given rise to the very difficult project of giving a semantic theory that deals satisfactorily with propositional-attitude reports.

Frege offered a solution based on his sense/reference distinction. In addition to extensional entities (individuals, sets, and relations-in-extension) he postulated senses or modes of presentation, which we now sometimes call intensions, and which are, roughly, ways of determining referents. Briefly, in

attitude contexts, ‘Superman’ and ‘Clark Kent’ do not refer to their ordinary referents, but to their ordinary senses. Since ‘Superman’ and ‘Clark Kent’ refer to different senses in (1) and (2), we shouldn’t expect to substitute them *salva veritate*. In this way Frege preserves the principle of substitution, but at a cost. First, he introduces intensions, which seem to many to be dubious entities (Quine, 1961). Second, he violates Davidson’s (1968) requirement of ‘semantic innocence’ – that expressions should have the same semantic values in all contexts.

ILF theories aim to offer a semantic theory of propositional-attitude reports that can avoid these supposed problems. They aim to give a purely extensional semantics for attitude contexts, while preserving semantic innocence. Achieving these aims would make them extremely attractive. (See Larson and Segal, 1995: 437 for their rejection of intensional strategies for preserving semantic innocence.)

ILF theories are standardly embedded in a Davidsonian truth-theoretic semantics for natural language. The introduction of ILFs allows one to provide truth conditions for sentential complements embedded in propositional-attitude reports **within** the truth-theoretic-semantics framework. (For a clear explanation of why the Davidsonian framework (without ILFs) is not adequate to capture the truth conditions of propositional-attitude reports, see Larson and Segal, 1995: 415–418.)

What Are ILFs?

The basic idea is that propositional-attitude verbs express relations between an agent and an ‘interpreted logical form.’ The ‘logical form’ part of an ILF is, roughly, a sentential complement (a syntactic item), which usually takes one of the following forms: ‘a is F,’ ‘a’s being F,’ or ‘that a is F.’ (Lexical items are part of an expression’s logical form.) The ‘interpretation’ part of an ILF is the assignment of referents to parts of the sentential complement. ILFs can be represented with phrase structure trees whose terminal nodes are pairings of the relevant lexical items with their referents, and whose nonterminal nodes are pairings of the relevant phrasal categories with their referents. Simplifying, the sentential complement in an attitude reports such as

- (3) Lois believes John is funny

receives the following ILF:

<S, True>	
<NP, John>	<VP, John>
<‘John’, John>	<‘Funny’, John>

In a nutshell, ILFs are a combination of syntactical (linguistic) and referential (nonlinguistic) material – they are hybrids relative to purely syntactical approaches and purely referential approaches. (See Larson and Segal, 1995: 419–422 for a discussion of purely syntactical approaches.) Since ILFs conjoin only lexical items and extensional referents, ILF theories provide a purely extensional semantics for propositional-attitude reports.

Puzzles and Problems

An adequacy test for any semantics of the attitudes is how well it does in solving traditional puzzles. To begin, consider the way in which the linguistic and nonlinguistic features of ILFs allow them to solve one puzzle involving names and one puzzle involving demonstratives. I call these the ‘simple name puzzle’ and the ‘simple demonstrative puzzle.’ (The use of the term ‘simple’ here is of course theory relative. Russellians (e.g. Salmon, 1986, and Soames, 1987) have great difficulty with name puzzles.)

The Simple Name Puzzle

Most agree that the following two belief reports can differ in truth value, despite the fact that ‘Fido’ and ‘Rex’ refer to the same dog (this is a variant of the aforementioned Clark Kent/Superman case):

- (4) John believes that Fido barks.
(5) John believes that Rex barks.

John, for example, may only know the dog by the name ‘Fido’ and so only believe (4). Because ILFs are partly constituted by lexical items, the ILF theory can easily account for the difference in truth value between (4) and (5). Since ‘Fido’ and ‘Rex’ are different lexical items, the ILFs associated with the sentential complements in (4) and (5) will be different.

The Simple Demonstrative Puzzle

Consider

- (6) John believes that that is funny

used to report John’s referring to a comedian’s skit with the use of the embedded demonstrative. Now consider (6) used to report John’s referring to a TV show with the embedded demonstrative: clearly a different belief report. A purely sententialist theory of the attitudes (one that appeals only to syntactical items) has difficulty accounting for this difference. In both instances, John would be standing in relation to the same sentential complement, ‘that is funny.’ Since ILFs contain the referents of lexical items, they can easily account for differences between belief reports

that share sentential complements. In this case, one ILF would contain the comedian's skit as the semantic value of the embedded 'that,' and the other would contain the TV show.

These two puzzles show the power of ILF theories. The lexical features of ILFs allow them to be fine-grained enough to solve simple name puzzles without postulating intensional entities. The objectual features of ILFs prevent them from being too coarse-grained (as purely syntactical theories are) to solve simple demonstrative puzzles.

Consider now two further puzzles that prove to be more difficult for ILF theories. I call these 'the hard name puzzle' and 'the hard demonstrative puzzle.'

The Hard Demonstrative Puzzle

Suppose that John assents to

(7) That is a philosopher

while pointing to his professor in philosophy class (context 1), but denies (7) while pointing to a man seen from behind (he doesn't know it's his professor) at a party (context 2). Relative to these different contexts, then, intuitively,

(8) John believes that that is a philosopher

according to the context in which it is uttered, can differ in truth value. On its face, since the sentential complement, 'that is a philosopher,' and the referents assigned to its parts are the same in both contexts, ILF theories appear unable to account for the possible difference in truth value.

Larson and Ludlow (1997) respond to the hard demonstrative puzzle by appealing to a Burgean (1974) idea about the semantic values of demonstratives: according to Burge, the semantic value of a demonstrative is a pairing of what is demonstrated and the act of demonstration. By including acts of demonstration in the semantic value of demonstratives in attitude contexts, Larson and Ludlow can account for the truth value differences of (8) since the acts of demonstration will be different in the two contexts. Relative to context 1 the semantic value of the demonstrative will be $\langle x, a1 \rangle$, where x is the philosopher and $a1$ is the speaker's demonstrative act, and relative to context 2 the semantic value will be $\langle x, a2 \rangle$ where $a2$ is a distinct demonstrative act from $a1$.

Pietroski (1996) argues that it is unclear whether this response is nonFregean and well motivated. That is, Pietroski observes that acts of demonstration can affect the truth of (8) but not the truth of (7). This, he claims, concedes the Fregean point that a demonstrative way of thinking of a referent affects the truth

value of a sentence with an **embedded** demonstrative. Pietroski suggests that Larson and Ludlow can avoid this complaint by agreeing with Burge (1974), on grounds independent of attitude contexts, that the semantic values of demonstratives are **always** ordered pairs of the thing demonstrated and the act of demonstration.

A suggestion made by Higginbotham (1991) may provide an alternative way of dealing with cases like (8). In discussing an objection to both Creswell's (1985) structured meanings account of the attitudes and Larson and Ludlow's theory of ILFs, Higginbotham argues that both fail to include a crucial parameter in their accounts: "... namely that complement sentences are to be understood as if their speakers said them" (1991: 352). Lau (1995) argues that applying this parameter to (7), relative to context 1, in uttering (7) John would understand himself as referring to his philosophy professor and (8) would turn out true, but relative to context 2, John would not understand himself as referring to his philosophy professor and (8) would turn out false. Although this suggestion accounts for this case, more would need to be said about how this new parameter should be incorporated into the semantics.

The Hard Name Puzzle

Kripke's (1997) Paderewski case (and others like it) pose a more difficult challenge for ILF theories. Suppose John comes to know his shy neighbor, who never plays music at home and does not own a piano, as 'Paderewski.' Thus (9) is true:

(9) John does not believe that Paderewski is a pianist.

John also attends many concerts where he meets his favorite pianist, also called 'Paderewski.' Although these are the same Paderewski, John does not realize this. So, it is also true that

(10) John believes that Paderewski is a pianist.

There seems to be no way of distinguishing John's beliefs either in terms of lexical items (since there is only one linguistic item, 'Paderewski') or in terms of semantic values (since there is only one referent, Paderewski). So ILF theories apparently attribute contradictory beliefs to John.

The different responses to this puzzle (and the complexity of some of them) are evidence that it is particularly difficult for ILF theories. Larson and Ludlow (1993) suggest that although (9) and (10) contain the homophonous 'Paderewski,' there are really distinct syntactical items in play – 'PaderewskiI' and 'PaderewskiII' (much as there are distinct

syntactical items associated with 'bank'). They argue that since there are actually two names in (9) and (10), different ILFs would be assigned to them, thus avoiding the assignment of contradictory beliefs to John.

Many (e.g., Forbes, 1996; Taylor, 1995; Richard, 1990) have found this response implausible. They argue that unlike the term 'bank,' there is only one name 'Paderewski' in our common language. John certainly doesn't seem to have had a private baptism, introducing two names into his idiolect; rather he picked up the name in the ordinary way. Since he picked up the name in the ordinary way, and our language only has one name, John is using only one name. (See Pietroski, 1996: 366–368 for a different objection to Larson and Ludlow's solution to the Paderewski puzzle.)

Ludlow (2000) attempts a different response to the Paderewski puzzle, arguing that it dissolves on a correct understanding of language and the goals of ascribing propositional attitudes. First, language is not an external, social object, but what Chomsky (1986) calls an I-language – each person has her own lexicon, relying on substantial overlap with others for communication. Second, in ascribing propositional attitudes we are not trying to describe what is going on in an agent's head. Rather, we are helping a hearer construct a theory of an agent's mental life. Our focus, therefore, should be on the relationship between the ascription and the hearer, not on the ascription and the bearer of the attitude. Working with the hearer is a complicated process that involves theories of tacit belief, of goals of belief ascription, and of belief ascription logistics. But most importantly for Paderewski cases, the speaker and hearer are engaged in a negotiation about the best expressions for ascribing a propositional attitude to the agent. In Paderewski cases we need some way of distinguishing between an agent's beliefs, and the speaker and hearer negotiate this by choosing distinct expressions. Signaling John's beliefs about Paderewski *qua* piano player will involve an appropriate choice of expression – perhaps speaker and hearer will use the expression 'Paderewski *qua* piano player.' Similarly for John's beliefs about Paderewski *qua* shy neighbor. The upshot is that we do not get a straightforward contradiction of the form (Fa & ~Fa) – our different I-languages grant us fluidity with our lexicons, making contradictions across discourses unlikely.

Prospects

Interestingly, this response to the Paderewski case is related to another common complaint about ILF theories. Maintaining that ILFs are partly constituted

by English lexical items results in several related difficulties: if a monolingual French speaker believes that Fido barks, he does not believe an ILF with English expressions; ILF theories seem incapable of capturing the idea that English and French speakers believe the same thing (or something very similar) when they believe that Fido barks; phonetically distinct sentential complements cannot co-refer. These problems result from the plausible idea that a semantic theory ought to capture what is grasped in understanding sentences of a language; and speakers using different languages can presumably grasp the same thing. This immediately forges a close link between the objects of the attitudes and the semantics of attitude ascriptions.

These problems may be dealt with semantically or pragmatically. Davidson (1968), Lepore and Loewer (1989) and Higginbotham (1986) suggest a semantic solution by building a notion of same-saying or similarity into the truth conditions for attitude reports. Agents stand in intentional relations to ILFs similar to (or that say the same thing as) those involving English lexical items. The similarity or same-saying relation provides a way of capturing what is common among thinkers across languages and thinkers without linguistic abilities. This is accomplished by indicating a close relation between the theory of propositional attitudes and the semantics of attitude ascriptions.

Larson and Ludlow (1997), Larson and Segal (1995), and Larson (2000) offer a pragmatic solution. Similarity of propositional attitude or same-saying is a matter of usage, not content: it is a pragmatic matter whether two propositional-attitude sentences can be used to report the same attitude. The form of this pragmatic solution has been cast in different ways. In Larson and Ludlow (1997), choosing the best propositional-attitude sentence is based on the same considerations Ludlow (2000) appealed to in addressing the Paderewski puzzle: speaker and hearer work out the best attitude ascriptions based on theories of tacit belief, goals of belief ascription, and belief ascription logistics. Larson and Segal (1995) rely on the notion of **expression** to elucidate their pragmatic solution. In short, when an ILF is used to report an agent's belief, it is not that an agent is standing in a relation to an ILF; rather, the ILF is **used to express** what the agent believes: "to believe an ILF is to have a belief expressed by it, to desire an ILF is to have a desire expressed by it, and so on" (Larson and Segal, 1995: 445). Explicating believing and desiring in terms of the notion of expression is not part of the semantics – it is an explanation of what believing and desiring an ILF involves. So, to believe that grass is green is to **believe an ILF**, which means to have a belief that is expressed by

that ILF. But what does an ILF express? The answer to this question seems to present ILF theorists with a dilemma. Either an ILF expresses a proposition, something that transcends any specific language, or an ILF expresses something that involves English expressions. The first horn of the dilemma seems to lead in the direction of Fregean propositions, and the second horn of the dilemma does not seem capable of capturing what a French speaker believes.

In summary, ILFs are combinations of linguistic items and nonlinguistic items. Their linguistic features are at once their most coveted and their most objectionable feature. They provide a solution to a traditional name puzzle without postulating intensional entities. But if the semantics of attitude reports indicate what we stand in relation to when we believe, desire, and hope, it is problematic to appeal to English expressions. If one chooses a semantic solution to this problem, building a similarity or same-saying relation into the truth conditions, then a careful consideration of these relations is required. If one chooses a pragmatic solution, one must decide whether one has given up too much in surrendering the idea that the semantics of attitude reports overlaps in a natural way with the theory of the attitudes.

Irony

S Attardo, Youngstown State University, Youngstown, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'irony' is commonly used to describe both a linguistic phenomenon (verbal irony) and other phenomena including 'situational' irony (i.e., irony of facts and things dissociated from their linguistic expression; Shelley, 2001) such as a fire-station burning to the ground, various more-or-less philosophical ideas (Socratic irony, Romantic irony, Postmodern irony), and even a type of religious experience (Kierkegaard, 1966). While there may be connections between situational and verbal irony, it does not appear that literary and religious uses can be fruitfully explained in terms of linguistic irony. This treatment will be limited to verbal irony.

Other definitional problems include the purported distinction between irony and sarcasm. While some have argued that the two can be distinguished (for example, irony can be involuntary, while sarcasm cannot be so), others maintain that no clear boundary exists. A further problem is presented by the fact that in some varieties of English, the term *irony* is undergoing semantic change and is assuming the meaning of an unpleasant surprise, while the semantic space previously occupied by *irony* is taken up by the term *sarcasm*.

The word *irony* goes back to the Greek *eironeia* (pretense, dissimulation) as does the history of its definition and analysis. Irony is seen as a trope (i.e., a figure of speech) in ancient rhetorics and this analysis has remained essentially unchallenged until recently. In the traditional definition irony is seen as saying something to mean the opposite of what is said. This definition is demonstrably incorrect, as a speaker may be ironical but not mean the opposite of what he/she says; cf. *It seems to be a little windy* (uttered in the middle of a violent storm), in which the speaker is saying less than what is meant. Similarly, overstatements and hyperbole may be ironical (Kreuz and Roberts, 1995).

A recent and fruitful restatement of the irony-as-trope theory has been presented by Paul Grice who sees irony as an implicature, i.e., as a deliberate flouting of one of the maxims of the principle of cooperation. Relatedly, speech-act approaches to irony see it as an insincere speech act. Initially, Grice's approach saw irony as a violation of the maxim of quality (i.e., the statement of an untruth) but this claim has been refuted, as seen above. Broadening the definition to, for example, 'saying something while meaning

something else,' runs the risk of obliterating the difference between irony and other forms of figurative or indirect speech. However, this loss of distinction may be a positive aspect of the definition, as has been recently argued (Kreuz, 2000, Attardo, 2002).

While the idea of 'oppositeness' in irony is problematic, approaches to irony as negation have been presented (Giora, 1995), who sees irony as 'indirect' (i.e., inexplicit; cf. Utsumi, 2000) negation; related ideas are that of contrast (Colston, 2002) and inappropriateness (Attardo, 2000).

A very influential approach to irony is the mention theory (Sperber and Wilson, 1981), which claims that an utterance is ironical if it is recognized as the echoic mention of another utterance by a more or less clearly identified other speaker. Furthermore, the ironical statement must be critical of the echoed utterance (cf. Grice, 1989: 53–54). Similar theories based on the ideas of 'pretense' and 'reminder' have been presented as well. Criticism of the mention theory notes that not all irony seems to be interpretable as the echo of someone's words, or that if the definition of mention is allowed to encompass any possible mention it becomes vacuous (since any sentence is potentially the mention of another sentence). Furthermore, there exists an admittedly rarer, non-negative, praising irony, called *asteism* (Fontanier, 1968: 150). An example of *asteism* might be a colleague describing Chomsky's *Aspects of the theory of syntax* as a 'moderately influential' book in linguistics. Other approaches to irony include the 'tinge' theory, which sees irony as blending the two meanings (the stated and the implied ones) with the effect of attenuating the ironical one (Colston, 1997).

All the theories of irony mentioned so far share the idea that the processing of irony is a two-step process in which one sense (usually assumed to be the literal meaning) of the utterance is accessed and then a second sense of the utterance is discovered (usually under contextual pressure). Thus, for example, in a Gricean account of irony as implicature, the hearer of an utterance such as *That was smart* (uttered as a description of clumsy behavior, such as spilling one's wine upon someone's clothing) will first process the utterance as meaning literally roughly 'This behavior was consonant with how smart people behave' and then will discard this interpretation in favor of the implicature that the speaker means that the behavior was *not* consonant with how smart people behave. This account has been challenged recently by 'direct access' theories.

The direct access theories claim that the hearer does not process the literal meaning of an ironical

utterance first and only later accesses the figurative (ironical) meaning. Rather, they claim that the literal meaning is either not accessed at all or only later. Direct access interpretations of irony are squarely at odds with the traditional interpretation of irony as an implicature. Some results in psycholinguistics have been seen as supporting this view (Gibbs, 1994). The mention theory of irony was commonly interpreted as a direct access theory, but recent work (Yus, 2003) seems to indicate that it too can be interpreted as a two-step process. Other researchers (e.g., Dews and Winner, 1999) have presented contrasting views which support the two-step approach, although not always the claim that the literal meaning is processed first: claims that interpretations are accessed in order of saliency (Giora, 2003) or in parallel have been put forth.

Psycholinguistic studies of irony have focused on children's acquisition of irony (Winner, 1988), progressively lowering the age at which children understand irony to under ten years old; on the neurobiology of the processing of irony (McDonald, 2000), emphasizing the role of the right hemisphere alongside the left one (in which most language processing takes place); and on the order of activation of the various meanings in the ironical text. A significant issue is the degree and nature of the assumptions that the hearer and speaker must share for irony to be understood; this can be summed up as the 'theory of mind' that the speakers have. In particular, irony involves metarepresentations (Bara *et al.*, 1997, Curcó, 2000).

Considerable attention has been paid to the optional markers of irony, i.e., primarily intonational and kinesic indications of the speaker's ironical intent. While several phonological and other features have been considered 'markers' of irony, it appears that none of these features is exclusively a marker of irony. Reviews of markers include phonological (e.g., intonation), graphic (e.g., italics, punctuation), morphological (e.g., quotatives), kinesic (e.g., winking), and contextual clues (Haiman, 1998).

Recently, the social and situational context of irony as well as its pragmatic ends have begun being investigated in sociolinguistics and discourse/conversation analysis as well as in psycholinguistics. Work on the social functions of irony has found a broad range of functions, including in- and out-group definition, evaluation, aggression, politeness, verbal play, and many others (e.g., Clift, 1999; Anolli *et al.*, 2002; Gibbs and Colston, 2002; Kotthoff, 2003). It is likely that this list may be open-ended.

The relationship between irony and humor remains underexplored, despite their obvious connections, although some studies are beginning to address the interplay of irony and other forms of implicature, such

as indirectness, and metaphoricity. Finally, it is worth noting that dialogic approaches to language (e.g., Ducrot, 1984) see irony as a prime example of the co-presence of different 'voices' in the text, in ways that avoid the technical problems highlighted in the mention theories.

Language as an Object of Study

Words are the leaves of the tree of language, of which,
if some fall away, a new succession takes their place.
– Field Marshall John French

What are the properties of language that make it similar to a tree? Could language exist without words in the way a tree may exist without leaves? Could words exist without the tree of language? One way to address these and other similar questions might be to make a list of the main properties of trees. The next step might be to look systematically for identical or similar properties in human languages. This would mean that our knowledge of botany would be guiding our scientific investigation of language. As fundamental differences between trees and languages are many and easily observable, it is evident that this research program does not hold enough promise to be worth pursuing. However, this general approach illustrates an important point about the methodology of scientific research in general and linguistic investigation of language in particular: research into one poorly understood object of study proceeds on the assumption that it shares its essential properties with some other (type of) object which is already better understood. In fact, some major landmarks in the development of modern linguistics are based on four conceptions of language as an object of study: language as a social fact, language as behavior, language as a mental organ, and language as an abstract object.

Language as a Social Fact

The view of language as a social fact, as suggested by Ferdinand de Saussure (1916), marked a shift away from the predominantly historical interest in language toward the study of language as a system at the current stage of its development. Saussure believed that important insights into language could be gained if it was investigated from the point of view of its users, who typically do not know anything about its historical

development. Since language use reflects the structure of language as a system of units at a particular stage of its development, language should be studied from the synchronic, rather than the diachronic, perspective. Saussure compared a given stage in the development of a language with the configuration of pieces on the chess board at a given stage of a game of chess. Just as the value of each piece is determined by its position relative to all the other pieces on the board (at a given stage of the game), a particular language at a given stage of development is a system of language units, or language signs (Saussure's term is *signe linguistique*), whose values are determined by their position in relation to all the other signs in the language system at that particular stage. And just as any change in the position of a given chess piece alters the values of all the other pieces and affects the system as a whole, the change that directly affects one language sign (potentially) affects the language system as a whole. For example, although the Serbian word 'jeftin' has the same meaning as the English word 'cheap,' it does not have the same value in the language system, because, in English, 'cheap' contrasts with 'inexpensive,' whereas in Serbian the same contrast is not lexicalized, so that it is either ignored, with 'jeftin' covering both meanings, or it is conveyed in some more elaborate way. The value of the Serbian word 'jeftin,' – its position in the language system – would change significantly if the equivalent of the English 'inexpensive' were to become lexicalized in Serbian.

In Saussure's view, language is a social fact akin to other social institutions, such as the legal system or the dress code. Although people's use of language reflects its systematic character, the structure of language as a system is not directly observable or consciously represented by its users. Saussure posited a distinction between observable linguistic behavior, what he called *parole* (speaking), and the underlying language system, what he called *langue* (language). In his view, the main task of linguistics was to discover *langue* – the language system – by investigating *parole* – language in use. Saussure's view of languages as a social fact is consistent with Émile Durkheim's

sociological theory (popular at the time when Saussure was developing his ideas on language), in which social facts are characterized as representations in the ‘collective mind,’ rather than as material or psychological entities.

Saussure’s concept of *langue* as a social fact, and as the proper object of linguistic investigation, had an unfortunate consequence. If *langue* is a system of relations between language signs, which are both external to its users and not directly observable in the manifestations of *langue* in use (because they are part of the ‘collective mind’), there is no place for the category of sentence in linguistic analysis. In other words, it follows from Saussure’s position that sentences are an aspect of *parole* rather than *langue*. Therefore, they are not a part of the systematic character of a language. So, although we readily produce and comprehend utterances of sentences that we have never produced or heard before and, although we assign them meanings in a systematic way, Saussure’s view of language as a social fact did not adequately accommodate this important aspect of language.

Language as Behavior

The view of language as behavior emerged in American descriptivist linguistics under the influence of positivism (in philosophy) and behaviorism (in psychology). An important methodological stance of logical positivism is that scientific research must be based either on statements that are tautologically true, such as: either P or not P, or they must be based on direct observation. The immediate consequence of this view for the scientific study of language was that all analyses and generalizations should be based strictly on the description of observable linguistic behavior. The main methodological stance of behaviorist psychology was that scientific theories could be refuted only by observable phenomena. Hence the descriptivists’ view that insights into language should be firmly grounded in observable data – the products of linguistic behavior – and that they should not be informed by the researcher’s introspection or the native speaker’s intuition. This meant that more attention was paid to particular languages than to the universal properties of human language, as we can only have direct data from particular languages. However, although descriptivist linguists initially thought of human languages as infinitely diverse, by the 1950s their interest had shifted towards the possibility of devising a discovery procedure, a mechanism that would take a corpus of utterances as input and yield a grammar as output (Harris, 1951).

The most important theoretical tenet of behaviorism was that all human behavior could be explained in terms of stimuli and responses to stimuli without reference to mental structures and processes. This stance had two major implications for the study of language: first, language was characterized as “the totality of utterances that can be made in a speech community” (Bloomfield, 1928). Second, since meaning is not directly observable and it could not be studied without reference to intuitive, introspective judgments, it was considered not to be the proper object of linguistics. Though to a lesser extent than Saussure’s conception of language as a social fact, the view of language as the product of behavior (especially in the early stages) also tended to focus on the phonological and morphological analysis of language, rather than on the less directly observable structural relations between words within sentences.

Language as a Mental Organ

The view of language as a mental organ is central to the most influential modern linguistic theory, the generative approach to language, developed by Noam Chomsky since the 1950s and his many followers (see Chomsky, 1986, 1988, 2000). Although the system of ideas that characterizes present-day generative linguistics is very complex, the basic assumptions on the nature of language are clearly established and they appear to be fundamentally commonsensical.

The idea that language is a mental organ is best illustrated by an analogy with other biologically specified properties of human beings. The development of any organism is partly determined by its genetic makeup and partly by environmental factors. For example, the onset of puberty and the height of a person are genetically determined, but they are also affected to some limited extent by external factors, such as nutrition. Given the diversity of environmental circumstances in which people grow up, and the uniformity in their physical appearance, there can be hardly any doubt as to the primacy of genetic makeup over the environment. The same observation carries over to our mental capacities. For example, numerical ability is unique to humans, who develop it in a uniform way regardless of the differences in their sociocultural and physical environments. Similarly, the design features of language, such as recursion, arbitrariness, and duality of patterning, cannot be explained as the result of environmental factors. Therefore, we should assume that both our ability to count and our linguistic ability are genetically specified. In other words, just as arms and legs are physical organs, language is a mental organ. The interaction

with the environment triggers the development of language, but the environmental inputs are simply not sufficiently structured for it to be plausible to assume that language development involves the construction of more and more detailed mirror images of the external world. Other comparable capacities would include our musical ability and the ability to construct scientific theories.

If language is a mental organ, then linguistics should be seen as a discipline of psychology, ultimately biology. It should aim to discover the abstract properties of language that make it possible to answer the following questions:

1. What do we know when we know language?
2. How is knowledge of language acquired?
3. How is this knowledge of language put to use?

In this view, the knowledge of language is characterized as a (generative) grammar: a finite system of interacting rules and principles that specify (more technically, generate) an infinite number of expressions, each of which is a structural configuration (e.g., of words into phrases and sentences) associated with a phonetic form and meaning. At the core of our ability to acquire language lie some universal innate properties of grammar, which guide the child's language development. The innate properties of grammar constrain the range of possible grammars of language and enable the child to find out which of the possible grammars is best evidenced by the linguistic behavior of those around him. This genetic endowment enables the child to go beyond the evidence presented by the data in determining the grammar. For instance, a child acquiring English figures out that 'John is too stubborn to talk to' means, roughly, 'John is so stubborn that nobody can talk to him' without explicit instruction and without being distracted by the possible analogy with utterances like 'John is too stubborn to talk to Bill,' which would be misleading. Therefore, evidence from language acquisition supports the view that the child constructs the grammar on the basis of innate mental structures that heavily constrain the range of available choices at any given stage of his linguistic development. The question of how knowledge of language is put to use is investigated by designing 'performance models' based on the mental grammar.

The research program of Chomskyan generative grammar differs in two important respects from those associated with the view of language as a social fact and the view of language as behavior. First, there is a shift of emphasis from the study of individual languages to the study of Universal Grammar (UG), where the latter is another name for language as a mental organ (in terms of the properties it identifies as

the set of grammars that a human being can learn under the conditions in which language acquisition normally takes place). Second, language as an object of study is an element of the mind, which Chomsky calls Internalized language (I-language). The approaches that consider language to be a social fact or behavior and the products of behavior are concerned with the study of language as external to the minds of its speakers. In Chomsky's terms, they are concerned with the study of Externalized language (E-language). Chomsky argues that E-languages (which correspond closely to what people normally mean when they speak about English, French, German, Chinese, Swahili, etc.) are epiphenomenal. In other words, they are complex constructs resulting from the interaction of various sociopolitical and historical factors. Therefore, understood in this way, a particular language like English or French is not a proper object of scientific investigation. Although people ordinarily speak about particular languages as individual objects that exist independently of individual speakers (in utterances like 'French is the language of diplomacy.'). Chomsky insists that this shift of focus from E-language to I-language is a shift towards the commonsense view of language, because when we say that a person knows a language we usually mean that they know how to relate sound patterns with meanings in a particular systematic way.

Language as an Abstract Object

In contrast to Chomsky's mentalist conception of language, Katz (1981) presents a detailed argument to support the view of language as an abstract object. The distinctive characteristics of abstract objects are (a) that their existence is independent of the existence of the mind, and (b) that they do not occupy a position in space and time. Presumably, natural numbers, which underlie the laws of nature, would exist even if human or other intelligence did not, and they are not located at particular places and times. In the light of these observations a natural language, such as English or Japanese, might seem a poor candidate for the category of abstract object. However, Katz (1981) argues that the task of writing the grammar of a language is too stringently constrained on Chomsky's requirement "that a grammar represent a language only in the particular form that knowledge of the language takes when such knowledge is realized in the human mind or brain" (Katz, 1981: 92). Arguably, this requirement has some unwelcome implications for linguistic analysis. For example, let us say that two grammars of a given language (G1 and G2) have been written. G1 reflects the speaker-hearer's

knowledge better than G2, but G2 is simpler and more elegant than G1. G1 and G2 are equivalent in all other respects. The question is: 'Is G1 to be preferred to G2, or is G2 to be preferred to G1?' In Katz's view it would be a mistake to reject G2 just because it is less psychologically plausible than G1. He points out the importance of the distinction between the knowledge of something and the object of knowledge itself. For example, natural numbers are distinct from the different ways in which they are represented in various calculators. By the same token, the speaker's knowledge of language is distinct from language itself. Chomsky (1986: 49) rejects this view with the following analogy between language and the heart as biological organs: the heart may be simply and elegantly described as a pump, disregarding what actually makes it beat as a part of the organism, but it does not follow that such a description would be superior to one which looks at the actual anatomy and physiology of the human heart. Therefore, if G2 is simpler and more elegant than G1, but G1 is more plausible as a psychologically real description of the speaker-hearer's knowledge of their language, then it is obvious that G2 should not be preferred to G1.

Katz also challenges Chomsky's view that individual languages are not proper objects of scientific study because they are sociopolitical constructs. In his view, this is "like claiming that the concept of number is not an object of mathematics but a sociopolitical one." (1981: 79–80). Chomsky (1986: 47) rejects this objection out of hand by describing it as a "curious conclusion" (for other criticisms and a defense against them, see Katz, 1985). Although some criticisms of Katz's view of language seem very convincing, a reasonably strong case can be made in support of the conception of language as an abstract object. On the one hand, the idea that language can be seen and studied scientifically as an abstract object does not entail that it is not also a psychological object. Hence, it is far from obvious that the only interesting and useful scientific approach to the study of language is psychological (biological). In other words, the conceptions of language as a mental organ and language as an abstract object might both provide the basis for credible scientific research. Moreover, the scientific study of various physical organs, such as the human heart, can easily draw on readily available evidence of their structure. By comparison, the evidence for the analysis and description of language as a mental organ is rather scant. Thus, if an organ, e.g., the human heart, were not available for relatively direct observation, then it would be perfectly sensible to investigate it by trying to figure

out the best abstract model in the hope that it would also turn out to be the one that corresponds most closely to the real thing. In fact, much work within Chomsky's generative approach in linguistics seems to proceed in this way. On the other hand, Katz (1985: 199–200) argues that theories of language grounded in individual psychology are not abstract enough to provide plausible explanations of language structure. His discussion of analytic sentences is particularly convincing. Analytic sentences, such as 'Nightmares are dreams.' and 'Flawed gems are imperfect.' are necessarily true in virtue of the semantic level of grammars. The Chomskyan approach, which characterizes the grammar in psychological terms, cannot provide an adequate account of necessary truths. 'Nightmares are dreams.' and 'Flawed gems are imperfect.' are true sentences, regardless of our psychological (biological) makeup, but, in the Chomskyan approach, these sentences have to be analyzed as necessarily true, because humans are psychologically (biologically) designed so that we cannot think of them as anything other than true statements. While this and related issues remain open for debate, there can be no doubt that Chomsky's psychological approach to language remains the most influential perspective from which it is studied within linguistics.

Lexical Conceptual Structure

J S Jun, Hankuk University of Foreign Studies,
Seoul, Korea

Introduction

The lexical conceptual structure (LCS) or simply the conceptual structure (CS) is an autonomous level of grammar in conceptual semantics (Jackendoff, 1983, 1990, 1997, 2002), in which the semantic interpretation of a linguistic expression is explicitly represented. Jackendoff's (1983) original conception is to posit a level of mental representation in which *thought* is couched (cf. the *language of thought* in Fodor, 1975). CS is a relay station between language and peripheral systems such as vision, hearing, smell, taste, kinesthesia, etc. Without this level, we would have difficulty in describing what we see and hear.

There are two ways to view CS in formalizing a linguistic theory. One is to view CS as a nonlinguistic system that serves as an interface between meaning and nonlinguistic modalities. Then, we need another level of representation for meaning (cf. Chomsky's [1981, 1995] LF); and CS is related to the linguistic meaning by pragmatics as shown in Figure 1. This is the view of Katz and Fodor (1963), Jackendoff (1972), Katz (1980), and Bierwisch and Schreuder (1992). The alternative conception is to view CS as the semantic structure. The linguistic meaning as well as nonlinguistic information compatible with sensory and motor inputs is directly represented in CS. CS is related with other linguistic levels such as syntax and phonology by correspondence rules, and therefore CS is part of the lexical information (*hence called*

LCS) as shown in Figure 2. This is the current view of conceptual semantics.

One argument that supports the latter view comes from generic judgment sentences. In the standard view of linguistic meaning, judgments of superordination, subordination, synonymy, entailment, etc., are *linguistic*. We judge that 'bird' and 'chicken' make a superordinate-subordinate pair; that in some dialects 'cellar' and 'basement' are synonymous; and that 'Max is a chicken' entails 'Max is a bird.' Linguistic judgments of this sort are formalized in theories such as meaning postulates (Fodor, 1975) and semantic networks (Collins and Quillian, 1969).

Jackendoff (1983) points out one problem in formalizing these judgments from a purely linguistic perspective: judgments of superordination and subordination, for instance, are directly related to judgments of generic categorization sentences such as 'A chicken is a bird.' The judgment about generic categorization is, however, not entirely linguistic or semantic, in that it behaves creatively enough to include ambiguous cases such as (1) below.

- (1a) A piano is a percussion instrument.
 - (1b) An australopithecine was a human.
 - (1c) Washoe (the chimp)'s sign system is a language.
 - (1d) An abortion is a murder.
- (Jackendoff, 1983: 102)

We make generic categorization judgments about (1) not on the basis of meaning postulates or semantic networks but on the basis of our factual, often political, world knowledge. For instance, our judgment about (1d) is influenced by our political position, religion, and knowledge about biology. This is analogous to Labov's (1973) dubious 'cup-bowl'

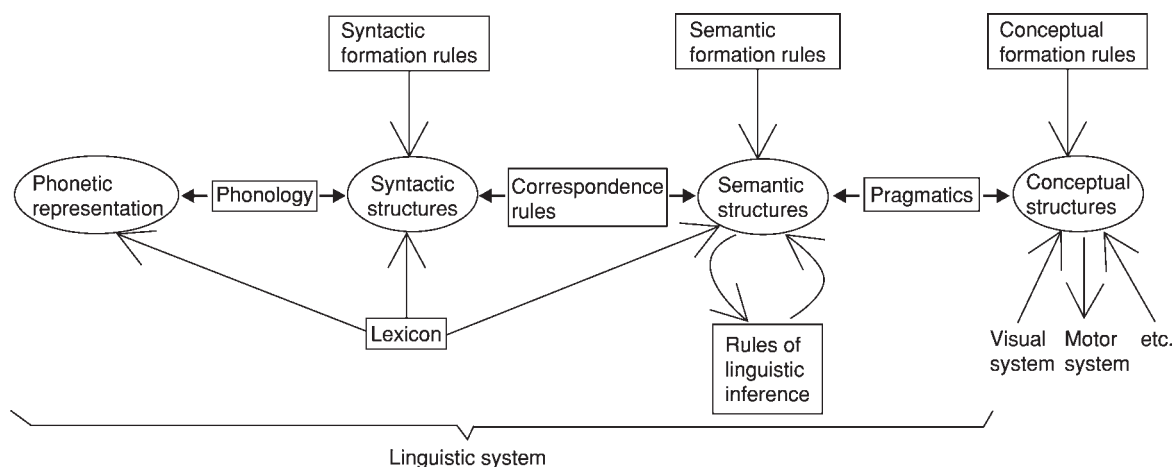

Figure 1 CS as a nonlinguistic system (adapted from Jackendoff R (1983). *Semantics and cognition*. Cambridge, MA: MIT Press, 20, with permission).

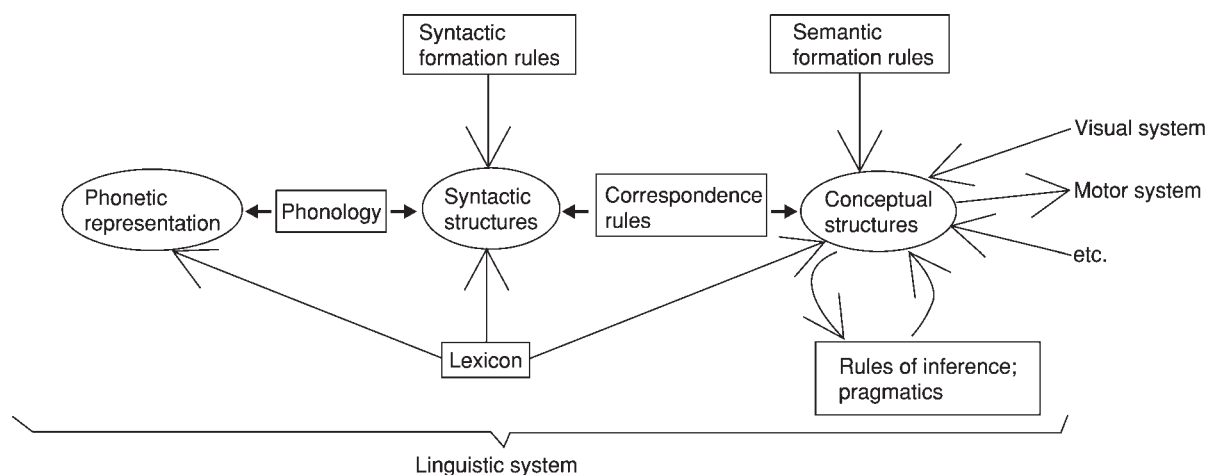

Figure 2 CS as part of the linguistic system (adapted from Jackendoff R (1983). *Semantics and cognition*. Cambridge, MA: MIT Press, 21, with permission).

judgment, which obviously resorts to nonlinguistic encyclopedic knowledge as well as the linguistic type system. CS is, by definition, the level that represents encyclopedic knowledge as part of our thought. Hence, we should refer to CS to make generic categorization judgments about (1).

Jackendoff's (1983) puzzle is summarized, as follows. We make judgments of semantic properties such as superordination and subordination at the level of semantic structure. We make generic categorization judgments at the level of CS as shown by (1). If the semantic structure were separated from CS, we would fail to catch the obvious generalization between the superordinate-subordinate judgment and the generic categorization judgment. If, by contrast, CS were the semantic structure, we would have no trouble in accounting for the intuitive identity between the two judgments. Therefore, CS is the semantic structure. For more arguments to support the view that CS is the semantic structure, see Jackendoff (1983: Ch. 6).

Overview of Conceptual Semantics

Autonomy of Semantics

A central assumption in conceptual semantics is the autonomy of semantics. In Chomsky's view of language, syntax makes an autonomous level of grammar, whereas phonology and semantics merely serve as interpretive components (PF and LF). Jackendoff (1997) criticizes this view as *syntactocentric*, and provides convincing arguments to support his thesis that phonology and semantics as well as syntax make autonomous levels of grammar.

We find numerous pieces of evidence for the autonomy of semantics in the literature of both psycholinguistics and theoretical linguistics. Zurif and Blumstein's (1978) pioneering work shows that Wernicke's area is the center of semantic knowledge in the brain in comparison with Zurif, Caramazza and Myerson's (1972) previous finding that Broca's area is the center of syntactic knowledge. Swinney's (1979) classical work on lexical semantic priming shows that lexical semantics is independent of the grammatical contexts like the movement chain in a sentence. Piñango, Zurif, and Jackendoff (1999) report more workload for the online processing of aspectual coercion sentences (e.g., *John jumped for two hours*) than for the processing of syntactically equivalent noncoerced sentences (e.g., *John jumped from the stage*).

Semantic categories are not in one-to-one correspondence with syntactic categories. For instance, all physical object concepts correspond to nouns, but not all nouns express physical object concepts; e.g., *earthquake* and *concert* express event concepts. All verbs express event/state concepts, but not all event/state concepts are expressed by verbs; e.g., *earthquake* and *concert* are nouns.

Contrary to Chomsky's (1981) theta criterion, we have plenty of data that shows mismatch between syntactic functions and thematic roles. For instance, the semantic interpretation of *buy* necessarily encodes both the transfer of money from the buyer to the seller and the transfer of the purchased entity from the seller to the buyer. Among the three semantic arguments, i.e., the buyer, the seller, and the purchased object, only the buyer and the purchased entity are syntactic arguments (e.g., *John bought the book*).

The seller is syntactically expressed as an adjunct (e.g., *John bought the book from Jill*). Moreover, the buyer plays the source role of money and the target role of the purchased entity simultaneously; the seller plays the source role of the purchased entity and the target role of money simultaneously. In short, the buyer and the seller have multiple theta roles even though each of them corresponds to one and only one syntactic entity.

A simple semantic distinction often corresponds to many syntactic devices. For instance, telicity is expressed by such various syntactic devices as choice of verb (2a), choice of preposition (2b), choice of adverbial (2c), choice of determiner in the subject NP (2d) and in the object NP (2e), and choice of prepositional object (2f) (Jackendoff, 1997: 35).

- | | |
|---|----------|
| (2a) John <i>destroyed</i> the cart (in/*for an hour). | → Telic |
| John <i>pushed</i> the cart (for/*in an hour). | → Atelic |
| (2b) John ran <i>to</i> the station (in/*for an hour). | → Telic |
| John ran <i>toward</i> the station (for/*in an hour). | → Atelic |
| (2c) The light flashed <i>once</i> (in/*for an hour). | → Telic |
| The light flashed <i>constantly</i> (for/*in an hour). | → Atelic |
| (2d) <i>Four people</i> died (in/*for two days). | → Telic |
| <i>People</i> died (for/*in two days) | → Atelic |
| (2e) John ate <i>lots of peanuts</i> (in/*for an hour) | → Telic |
| John ate <i>peanuts</i> (for/*in an hour). | → Atelic |
| (2f) John crashed into <i>three walls</i> (in/*for an hour) | → Telic |
| John crashed into <i>walls</i> (for/*in an hour) | → Atelic |

To sum up, the mapping between syntax and semantics is not one-to-one; rather, it is one-to-many, many-to-one, or at best many-to-many. The mapping problem is not easy to explain in the syntactocentric

architecture of language. The overall difficulty in treating semantics merely as an interpretive component of grammar along with a similar difficulty treating phonology as an interpretive component (cf. Jackendoff, 1997: Ch. 2) leads Jackendoff to propose a tripartite architecture of language, in which phonology, syntax, and semantics are all independent levels of grammar licensed by phonological formation rules, syntactic formation rules, and conceptual/semantic formation rules respectively, and interfaced by correspondence rules between each pair of modules, as shown in Figure 3.

Lexical Conceptual Structure

Conceptual semantics assumes striking similarities for the organization of CS with the structural organization of syntax. As syntax makes use of syntactic categories, namely syntactic parts of speech like nouns, adjectives, prepositions, verbs, etc., semantics makes use of semantic categories or semantic parts of speech such as Thing, Property, Place, Path, Event, State, etc. As syntactic categories are motivated by each category member's behavioral properties in syntax, semantic or ontological categories are motivated by each category member's behavioral properties in meaning.

Syntactic categories are combined by syntactic phrase-structure structure rules into larger syntactic expressions; likewise, semantic categories are combined by semantic phrase-structure rules into larger semantic expressions. The syntactic representation is

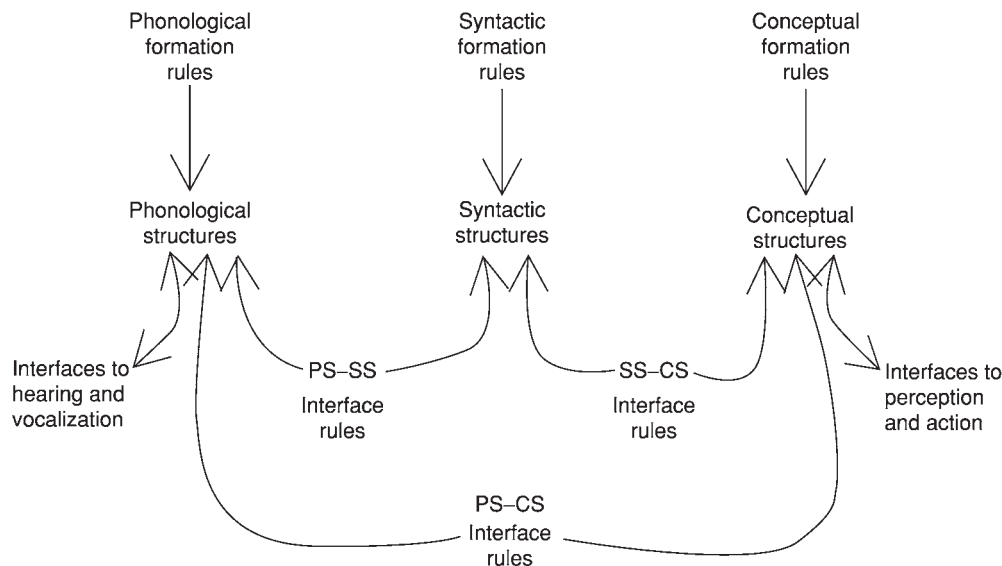

Figure 3 The tripartite parallel architecture (reproduced from Jackendoff R (2002). *Foundations of language: brain, meaning, grammar, evolution*. Oxford: Oxford University Press).

structurally organized, so we can define dominance or government relations among syntactic constituents; likewise, the semantic representation is structurally organized, so we can define grammatically significant hierarchical relations among semantic constituents. Various syntactic phrase-structure rules can be generalized into a rule schema called X-bar syntax (Jackendoff, 1977); likewise, various semantic phrase-structure rules can be generalized into a rule schema called X-bar semantics (Jackendoff, 1987b).

Ontological Categories Ontological categories are first motivated by our cognitive layouts. To mention some from the vast psychology literature, Piaget's developmental theory of *object permanence* shows that infants must recognize objects as a whole, and develop a sense of permanent existence of the objects in question when they are not visible to the infants. Researchers in language acquisition have identified many innate constraints on language learning like reference principle, object bias, whole object principle, shape bias, and so on (cf. Berko Gleason, 1997). For instance, children rely on the assumption that words refer to objects, actions, and attributes in the environments by reference principle. Wertheimer's (1912) classical experiment on *apparent movement* reveals that humans are equipped with an innate tendency to perceive the change of location as movement from one position to the other; the apparent movement experiment renders support for the expansion of the event category into function argument structures like $[_{Event} GO ([_{Thing}], [_{Path}])]$.

Ontological categories also have numerous linguistic motivations. Pragmatic anaphora (exophora) provides one such motivation. In order to understand the sentence in (3), the hearer might have to pick out the referent of *that* among several entities in the visual field. If the hearer did not have object concepts to organize the visible entities, (s)he could not pick out the proper referent of the pragmatic anaphora *that*. The object concept involved in the semantic interpretation of (3) motivates the ontological category Thing.

(3) I bought *that* last night.

The category Thing proves useful in interpreting many other grammatical structures. It provides the basis of interpreting the Wh-variable in (4a); it supports the notion of identity in *the same* construction in (4b); and it supports the notion of quantification as shown in (4c).

- (4a) *What* did you buy last night?
 (4b) John bought *the same thing* as Jill.

(4c) John bought *something/everything that Jack bought*.

Likewise, we find different sorts of pragmatic anaphora that motivate ontological categories like Place (5a), Direction (5b), Action (5c), Event (5d), Manner (5e), and Amount (5f).

- (5a) Your book was *here/there*.
 (5b) They went *there* yesterday.
 (5c) Can he do *this/that*?
 (5d) *It* happened this morning.
 (5e) Bill shuffled a deck of cards *this* way.
 (5f) The man I met yesterday was *this* tall.

These ontological categories provide innate bases for interpreting Wh-variables, the identity construction, and the quantification, as shown in (6)–(8).

- (6a) *Where* was my book?
 (6b) *Where* did they go yesterday?
 (6c) *What* can he do?
 (6d) *What* happened this morning?
 (6e) *How* did Bill shuffle a deck of cards?
 (6f) *How* tall was the man you met yesterday?
 (7a) John put the book on *the same place* as Bill.
 (7b) John went *the same way* as Bill.
 (7c) John did *the same thing* as Bill.
 (7d) *The same thing* happened yesterday as happened this morning.
 (7e) John shuffled a deck of cards *the same way* as Bill.
 (7f) John is *as tall as* the man I met yesterday.
 (8a) John put the book at *some place that Bill put it*.
 (8b) John went *somewhere that Bill went*.
 (8c) John did *something Bill did*.
 (8d) *Something that happened this morning* will happen again.
 (8e) John will shuffle cards in *some way that Bill did*.
 (8f) (no parallel for amounts)

For more about justifying ontological categories, see Jackendoff (1983: Ch. 3).

Conceptual Formation Rules Basic ontological categories are expanded into more complex expressions using function-argument structural descriptions. (9) shows such expansions of some ontological categories.

- (9a) EVENT \rightarrow $[_{Event} GO (THING, PATH)]$
 (9b) EVENT \rightarrow $[_{Event} STAY (THING, PLACE)]$
 (9c) EVENT \rightarrow $[_{Event} CAUSE (THING \text{ or } EVENT, EVENT)]$
 (9d) EVENT \rightarrow $[_{Event} INCH (STATE)]$
 (9e) STATE \rightarrow $[_{State} BE (THING, PLACE)]$
 (9f) PLACE \rightarrow $[_{Place} PLACE-FUNCTION (THING)]$
 (9g) PATH \rightarrow $[_{Path} PATH-FUNCTION (THING)]$

The function-argument expansion is exactly parallel with rewriting rules in syntax (e.g., $S \rightarrow NP VP$; $NP \rightarrow Det (AP)^* N$; $VP \rightarrow V NP PP$), and hence can be regarded as semantic phrase-structure rules. The semantic phrase-structure rules in (9) allow recursion such as syntactic phrase-structure rules: an Event category can be embedded in another Event category as shown in (9c). We also can define hierarchical relations among conceptual categories in terms of the depth of embedding as we define syntactic dominance or government in terms of the depth of embedding in syntactic structures. The depth of embedding in CS plays a significant role in explaining such various grammatical phenomena as subject selection, case, binding, control, etc. See Culicover and Jackendoff (2005) for more about these issues.

Place functions in (9f) may include IN, ON, TOP-OF, BOTTOM-OF, etc. Path functions in (9g) may include TO, FROM, TOWARD, VIA, etc. Conceptual semantics is a parsimonious theory, in that it makes use of only a handful of functions as conceptual primitives. All functions should be motivated on strict empirical grounds. This is exactly parallel with using only a handful of syntactic categories motivated on strict empirical grounds. Syntactic phrase-structure rules do not refer to unlimited number of syntactic categories. Syntactic categories such as noun, adjective, preposition, verb, etc. are syntactic primitives, and they are motivated by each category member's behavioral properties in syntax. Likewise, semantic phrase-structure rules refer to a restricted set of semantic or conceptual primitives that are empirically motivated by general properties of meaning.

Functions such as GO, BE, and STAY are empirically motivated in various semantic fields. They are the bases for interpreting spatial sentences in (10).

- (10a) GO: The train traveled from Boston to Chicago.
- (10b) BE: The statue stands on Cambridge common.
- (10c) STAY: John remained in China.

These functions also support the interpretation of possession sentences in (11).

- (11a) GO: John gave the book to Bill.
- (11b) BE: John had no money.
- (11c) STAY: The library kept several volumes of the Korean medieval literature.

Interpreting ascription sentences also require GO, BE, and STAY, as shown in (12).

- (12a) GO: The light turned from yellow to red.
- (12b) BE: The stew seemed distasteful.
- (12c) STAY: The aluminum stayed hard.

One interesting consequence of having GO, BE, and STAY in both spatial and nonspatial semantic fields is that we can explain how we use the same verb for different semantic fields.

- (13a) The professor turned into a driveway. (Spatial)
- (13b) The professor turned into a pumpkin. (Ascription)
- (14a) The bus goes to Paris. (Spatial)
- (14b) The inheritance went to Bill. (Possession)
- (15a) John is in China. (Spatial)
- (15b) John is a doctor. (Ascription)
- (16a) John kept the CD in his pocket. (Spatial)
- (16b) John kept the CD. (Possession)
- (17a) The professor remained in the driveway. (Spatial)
- (17b) The professor remained a pumpkin. (Ascription)

In (13), the verb *turn* is used in both spatial and ascription sentences with the GO meaning. How do we use the same verb for two different semantic fields? Do we have to assume two different lexical entries for *turn*? Conceptual semantics does not pay anything to explain this puzzle. We do not need two different lexical entries for *turn* to explain the spatial and ascription meanings. We just posit the event function GO for the lexical semantic description or LCS for *turn* in (13). Both spatial and ascription meanings follow from the LCS for *turn*, since the function GO is in principle motivated by both spatial and ascription sentences. We can provide similar accounts for all the data in (14)–(17). For more about the general overview of conceptual semantics, see Jackendoff (1983, 1987a, 1990, 2002).

X-bar Semantics

Generative linguists in the 1950s and 1960s succeeded in showing the systematic nature of language with a handful of syntactic phrase-structure rules. But they were not sure how the phrase-structure rules got into language learners' minds within a relatively short period of time; it was a learnability problem. X-bar syntax (Chomsky, 1970; Jackendoff, 1977) opened a doorway to the puzzle. Children do not have to be born with dozens of syntactic categories; children are born with one syntactic category, namely, category X. Children do not have to learn dozens of totally unrelated syntactic phrase-structure rules separately; all seemingly different syntactic phrase-structure rules share a fundamental pattern, namely, X-bar syntax.

Jackendoff (1987b, 1990), who was a central figure in developing X-bar syntax in the 1970s, has completed his X-bar theory by proposing X-bar semantics. We have so far observed that CS is exactly parallel with the syntactic structure. Conceptual categories are structurally organized into CS by virtue of semantic phrase-structure rules, as syntactic categories are structurally organized into syntactic structure by virtue of syntactic phrase structure rules. (18) is the basic formation of X-bar syntax.

- (18a) $XP \rightarrow \text{Spec } X'$
 (18b) $X' \rightarrow X \text{ Comp}$
 (18c) $X \rightarrow [\pm N, \pm V]$

Now that CS has all parallel properties with the syntactic structure, all semantic phrase-structure rules are generalized into X-bar semantics along the same line with X-bar syntax as shown in (19).

$$(19) [\text{Entity}] \rightarrow \begin{bmatrix} \text{Event Thing Place} \dots \\ \text{Token Type} \\ F(\langle \text{Entity}_1, \langle \text{Entity}_2, \langle \text{Entity}_3 \rangle \rangle \rangle) \end{bmatrix}$$

(19) provides not only the function-argument structural generalization for all the semantic phrase-structure rules but also shows how major syntactic constituents correspond to major conceptual categories. That is, the linking between syntax and semantics can be formalized as (20) and (21).

$$(20) XP \text{ corresponds to } [\text{Entity}]$$

$$(21) \begin{bmatrix} X_0 \\ \text{---} \langle YP \langle ZP \rangle \rangle \end{bmatrix} \underset{\text{to}}{\text{corresponds to}} \begin{bmatrix} \text{Entity} \\ F(E_1, \langle E_2, \langle E_3 \rangle \rangle) \end{bmatrix}$$

where YP corresponds to E_2 , ZP corresponds to E_3 , and the subject (if there is one) corresponds to E_1 .

To sum up, the obvious similarity between (18) and (19) enables us to account for the tedious linking problem without any extra cost.

General Constraints on Semantic Theories

Jackendoff (1983) suggests six general requirements that any semantic theory should fulfill: expressiveness, compositionality, universality, semantic properties, the grammatical constraint, and the cognitive constraint.

First, a semantic theory must be observationally adequate; it must be expressive enough to describe most, if not all, semantic distinctions in a natural language. Conceptual semantics has expressive power, in that most semantic distinctions in a natural language can be represented by CS with a handful of conceptual categories plus conceptual formation rules. What is better is that the expressive power has improved since the original conception of the theory. For instance, Jackendoff (1990: Ch. 7) introduced the action tier

into the theory to represent the actor/patient relation aside from motion and location. In (22a), *John* is the source of the *ball* and the actor of the throwing event simultaneously; the *ball* is a moving object, the theme, and an affected entity, the patient, simultaneously. It is quite common for one syntactic entity to bear double theta roles contra Chomsky's (1981) theta criterion; conceptual semantics captures this by representing the motion/location event in the thematic tier (22b), and the actor/patient relation in the action tier (22c).

- (22a) John threw the ball.
 Source Goal
 Actor Patient
 (22b) $[\text{Event CAUSE}([\text{JOHN}], [\text{Event GO}([\text{BALL}],$
 $[\text{Path TO}([\dots])]])]$
 (22c) $[\text{AFF}([\text{JOHN}], [\text{BALL}])]$

The action tier not only explains the fine semantic distinction in language but also plays a central role in such grammatical phenomena as linking and case. Besides the action tier, Jackendoff (1991) introduced an elaborate feature system into CS to account for the semantics of parts and boundaries; Csuri (1996) introduced the referential tier into CS that describes the definiteness of expressions; Jackendoff (2002) introduced the lambda extraction and the topic/focus tier into CS. All these and many other innovations make the theory expressive enough to account for significant portion of natural language semantics.

The second constraint on a semantic theory is compositionality: an adequate semantic theory must show how the meanings of parts are composed into the meaning of a larger expression. Conceptual semantics is compositional, in that it shows how combinatorial rules of grammar compose the meanings of ontological categories into the CS of a larger expression.

The third requirement is universality: an adequate semantic theory must provide cross-linguistically relevant semantic descriptions. Conceptual semantics is not a theory of meaning for any particular language. It is a universal theory of meaning; numerous cross-linguistic studies have been conducted with the conceptual semantic formalism. See Jun (2003), for instance, for a review of many conceptual semantic studies on the argument linking and case in languages such as Korean, Japanese, Hindi, Urdu, English, Old English, French, etc.

The fourth requirement is semantic properties: an adequate semantic theory should be able to explain many semantic properties of language like synonymy, anomaly, presupposition, and so on. That is, any semantic theory must explicate the valid inference of expressions. CS provides a direct solution to this problem in many ways. The type/token distinction is directly expressed in CS, and explains most semantic

distinctions made by the semantic type system. By decomposing verbs such as *kill* into [CAUSE ([THING], [NOT-ALIVE ([THING])])], conceptual semantics explains how *John killed Bill* entails *Bill is dead*. For more about semantic properties, see Jackendoff (1983, 1990, 2002).

The fifth requirement is the grammatical constraint: if other things were equal, a semantic theory that explains otherwise arbitrary generalizations about the lexicon and the syntax would be highly preferable. Conceptual semantics is a theory of meaning that shows how a handful of conceptual primitives organize the vast domain of lexical semantics. Conceptual semantics also explains how semantic entities are mapped onto syntactic entities in a principled manner. For instance, the linking principle in conceptual semantics states that the least embedded argument in the CS is mapped onto the least embedded syntactic argument, namely the subject. In (22b & c), [JOHN] is the least embedded argument in both the action and thematic tiers; this explains why [JOHN] instead of [BALL] is mapped onto the subject of (22a). Jun (2003) is a conceptual semantic work on case; Culicover and Jackendoff (2005) offer conceptual semantic treatments of binding, control, and many other syntax-related phenomena. In short, conceptual semantics is an interface theory between syntax and semantics. The theory has a desirable consequence for the learnability problem, too. Language learners cannot acquire language solely by syntax or solely by semantics. As Levin (1993) demonstrates, a number of syntactic regularities are predicted by semantic properties of predicates. Conceptual semantics makes a number of predictions about syntax in terms of CS. Chomsky's explanatory adequacy is a requirement for the learnability problem; conceptual semantics is thus a theory that aims to achieve the highest goal of a linguistic theory.

The final requirement on a semantic theory is the cognitive constraint: a semantic theory should address interface problems between language and other peripheral systems like vision, hearing, smell, taste, kinesthesia, etc. Conceptual semantics fulfills this requirement, as CS is by definition a level of mental representation at which both linguistic and non-linguistic modalities converge. Jackendoff (1987c) focuses on the interface problem, and shows, for instance, how the visual representation is formally compatible with the linguistic representation based on Marr's (1982) theory of visual perception.

Comparison with Other Works

Bierwisch and Schreuder's (B&S; 1992) work is another influential theory that makes explicit use of

the term *conceptual structure*. Conceptual semantics shares two important assumptions with B&S, but there are crucial distinctions between the two theories. First, B&S also assume a separate level of conceptual structure. Their conception of CS is similar to Jackendoff's conception of CS in that CS is a representational system of message structure where non-linguistic factual/encyclopedic information is expressed. B&S, however, assume that CS strictly belongs to a nonlinguistic modality, and that the linguistic meaning is represented in another level called *semantic form* (SF). As a result, SF, but not CS, is the object of lexical semantics, and hence LCS does not make much sense in this theory. In the first section of this article, we discussed two possible views of CS; B&S take the former view of CS, whereas Jackendoff advocates the latter view.

Second, SF in B&S's theory is compositional as CS in conceptual semantics. B&S's lexical decomposition relies on two sorts of elements: constants such as DO, MOVE, FIN, LOC, etc., and variables such as *x*, *y*, *z*. Constants and variables are composed into a larger expression in terms of formal logic. (23a) illustrates B&S's SF for *enter*; (23b) is the CS for the same word in Jackendoff's theory.

(23a) [*y* DO [MOVE *y*] : FIN [*y* LOC IN *x*]]

(23b) [_{Event} GO ([_{Thing}], [_{Path} TO ([_{Place} IN ([_{Thing}]))])])]

One reason B&S maintain a purely nonlinguistic CS as well as a separate SF is that factual or encyclopedic knowledge does not seem to make much grammatical contribution to language. To B&S, there is a clear boundary where the *semantic* and the *encyclopedic* diverge.

Pustejovsky's (1995) generative lexicon (GL) theory is interesting in this regard. GL also assumes lexical decomposition. Pustejovsky's lexical decomposition makes use of factual or encyclopedic knowledge in a rigorous formalism called the *qualia* structure. The qualia structure of *book*, for instance, expresses such factual knowledge as the origin of *book* as *write*(*x*, *y*) in the Agentive quale, where *x* is a writer (i.e., *human*(*x*)), and *y* is a book (i.e., *book*(*y*)). The qualia structure also expresses the use of the word in the Telic quale; hence, the lexical semantic structure for *book* includes such factual knowledge as *read*(*w*, *y*), where *w* is a reader (i.e., *human*(*w*)), and *y* is a book.

The factual or encyclopedic knowledge is not only expressed in formal linguistic representations but also plays a crucial role in explaining a significant portion of linguistic phenomena. We interpret (24) as either *Chomsky began writing a book* or *Chomsky began reading a book*. Pustejovsky suggests generative

devices like type coercion and co-composition to explain the two readings of (24) in a formal theory; i.e., *writing* or *reading* is part of the qualia structure of *book*, and, hence, the two readings of (24) are predicted by formal principles of lexical semantics.

(24) Chomsky began a book.

It is far beyond the scope of this article to discuss the GL theory in detail. But the success of the GL theory for a vast range of empirical data shows that the boundary between *semantic* and *encyclopedic* or between *linguistic* and *nonlinguistic* is not so clear as B&S assume in their distinction between CS and SF.

Suggested Readings

For a quick overview of conceptual semantics with one paper, see Jackendoff (1987a). For foundational issues of conceptual semantics, see Jackendoff (1983). For an overview of language and other cognitive capacities from a broad perspective, see Jackendoff (1987c). Jackendoff (1990) offers a comprehensive picture of conceptual semantics. Jackendoff (1997) is a bit technical, but it is important to set up the parallel architecture of language. For syntactic issues of conceptual semantics, see Jun (2003) and Culicover and Jackendoff (2005).

Lexical Semantics: Overview

Word Knowledge

Semantic interpretation requires access to knowledge about words. The lexicon of a grammar must provide a systematic and efficient way of encoding the information associated with words in a language. Lexical semantics is the study of what words mean and how they structure these meanings. This article examines word meaning from two different perspectives: the information required for composition in the syntax and the knowledge needed for semantic interpretation. The lexicon is not merely a collection of words with their associated phonetic, orthographic, and semantic forms. Rather, lexical entries are structured objects that participate in larger operations and compositions, both enabling syntactic environments and acting as signatures to semantic entailments and implicatures in the context of larger discourse.

There are four basic questions in modeling the semantic content and structure of the lexicon: (1) What semantic information goes into a lexical entry? (2) How do lexical entries relate semantically to one another? (3) How is this information exploited compositionally by the grammar? and (4) How is this information available to semantic interpretation generally? This article focuses on the first two.

The lexicon and lexical semantics have traditionally been viewed as the most passive modules of language, acting in the service of the more dynamic components of the grammar. This view has its origins in the generative tradition (Chomsky, 1955) and has been an integral part of the notion of the lexicon ever since. While the *aspects* model of selectional features (Chomsky, 1965) restricted the relation of selection to that between lexical items, work by McCawley (1968) and Jackendoff (1972) showed that selectional restrictions must be available to computations at the level of derived semantic representation rather than at deep structure. Subsequent work by Bresnan (1982), Gazdar *et al.* (1985), and Pollard and Sag (1994) extended the range of phenomena that can be handled by the projection and exploitation of lexically derived information in the grammar.

With the convergence of several areas in linguistics (lexical semantics, computational lexicons, and type theories) several models for the determination of selection have emerged that put even more compositional power in the lexicon, making explicit reference to the paradigmatic systems that allow for grammatical

constructions to be partially determined by selection. Examples of this approach are generative lexicon theory (Bouillon and Busa, 2001; Pustejovsky, 1995) and construction grammar (Goldberg, 1995; Jackendoff, 1997, 2002). These developments have helped to characterize the approaches to lexical design in terms of a hierarchy of semantic expressiveness. There are at least three such classes of lexical description: *sense enumerative lexicons*, where lexical items have a single type and meaning, and ambiguity is treated by multiple listings of words; *polymorphic lexicons*, where lexical items are active objects, contributing to the determination of meaning in context, under well-defined constraints; and *unrestricted sense lexicons*, where the meanings of lexical items are determined mostly by context and conventional use. Clearly, the most promising direction seems to be a careful and formal elucidation of the *polymorphic lexicons*, and this will form the basis of the subsequent discussion of both the structure and the content of lexical entries.

Historical Overview

The study of word meaning has occupied philosophers for centuries, beginning at least with Aristotle's theory of meaning. Locke, Hume, and Reid all paid particular attention to the meanings of words, but not until the 19th century did the rise of philological and psychological investigations of word meaning occur, with Bréal (1897), Erdmann (1900), Trier (1931), Stern (1931/1968), and others focused on word connotation, semantic drift, and word associations in the mental lexicon as well as in social contexts.

Interestingly, Russell, Frege, and other early analytic philosophers were not interested in language as a linguistic phenomenon but simply as the medium through which judgments can be formed and expressed. Hence, there is little regard for the relations between senses of words, when not affecting the nature of judgment, for example, within intensional contexts. Nineteenth-century semanticists and semasiologists, on the other hand, viewed polysemy as the life force of human language. Bréal, for example, considered it to be a necessary creative component of language and argued that this phenomenon better than most in semantics illustrates the cognitive and conceptualizing force of the human species.

Even with their obvious enthusiasm, semasiology produced no lasting legacy to the study of lexical semantics. In fact, there was no systematic research into lexical meaning until structural linguists extended the relational techniques of Saussure (1916/1983) and elaborated the framework of componential analysis for language meaning (Jakobson, 1970).

The idea behind componential analysis is the reduction of a word's meaning into its ultimate contrastive elements. These contrastive elements are structured in a matrix, allowing for dimensional analysis and generalizations to be made about lexical sets occupying the cells in the matrix.

This technique developed into a general framework for linguistic description called distinctive feature analysis (Jakobson and Halle, 1956). This is essentially the inspiration for Katz and Fodor's 1963 theory of lexical semantics within transformational grammar. In this theory, usually referred to as 'markerese,' a lexical entry in the language consists of grammatical and semantic markers and a special feature called a '*semantic distinguisher*.' In Weinreich (1972) and much subsequent discussion, it was demonstrated that this model is far too impoverished to characterize the compositional mechanisms inherent in language. In the late 1960s and early 1970s, alternative models of word meaning emerged (Fillmore, 1965; Gruber, 1965; Jackendoff, 1972; Lakoff, 1965) that respected the relational structure of sentence meaning while encoding the named semantic functions in lexical entries. In Dowty (1979), a model theoretic interpretation of the decompositional techniques of Lakoff, McCawley, and Ross was developed.

Recently, the role of lexical-syntactic mapping has become more evident, particularly with the growing concern over projection from lexical semantic form, the problem of verbal alternations and polyvalency, and the phenomenon of polysemy.

Ambiguity and Polysemy

Given the compactness of a lexicon relative to the number of objects and relations in the world, and the concepts we have for them, lexical ambiguity is inevitable. Add to this the cultural, historical, and linguistic blending that contributes to the meanings of our lexical items, and ambiguity can appear arbitrary as well. Hence, '*homonymy*' – where one lexical form has many meanings – is to be expected in a language. Examples of homonyms are illustrated in the following sentences:

- (1a) Mary walked along the bank of the river.
- (1b) Bank of America is the largest bank in the city.
- (2a) Drop me a line when you are in Boston.
- (2b) We built a fence along the property line.
- (3a) First we leave the gate, then we taxi down the runway.
- (3b) John saw the taxi on the street.
- (4a) The judge asked the defendant to approach the bar.
- (4b) The defendant was in the pub at the bar.

Weinreich (1964) calls such lexical distinctions '*contrastive ambiguity*,' where it is clear that the senses associated with the lexical item are unrelated. For this reason, it is generally assumed that homonyms are represented as separate lexical entries within the organization of the lexicon. This accords with a view of lexical organization that has been termed a '*sense enumeration lexicon*' (cf. Pustejovsky, 1995). That is, a lexicon is *sense enumerative* when every word *w* that has multiple senses stores these senses as separate lexical entries.

This model becomes difficult to maintain, however, when we consider the phenomenon known as '*polysemy*.' Polysemy is the relationship that exists between different senses of a word that are related in some logical manner rather than arbitrarily, as in the previous examples. We can distinguish three broad types of polysemy, each presenting a novel set of challenges to lexical semantics and linguistic theory.

- a. Deep semantic typing: single argument polymorphism
- b. Syntactic alternations: multiple argument polymorphism
- c. Dot objects: lexical reference to objects that have multiple facets

The first class refers mainly to functors allowing a range of syntactic variation in a single argument. For example, aspectual verbs (*begin* and *finish*), perception verbs (*see*, *hear*), and most propositional attitude verbs (*know*, *believe*) subcategorize for multiple syntactic forms in complement position, as illustrated in (6):

- (5a) Mary began to read the novel.
- (5b) Mary began reading the novel.
- (5c) Mary began the novel.
- (6a) Bill saw John leave.
- (6b) Bill saw John leaving.
- (6c) Bill saw John.
- (7a) Mary believes that John told the truth.
- (7b) Mary believes what John said.
- (7c) Mary believes John's story.

What these and many other cases of multiple selection share is that the underlying relation between the verb and each of its complements is essentially identical. For example, in (7), the complement to the verb *believe* in all three sentences is a proposition; in (5), what is begun in each sentence is an event of some sort; and in (6), the object of the perception is (arguably) an event in each case. This has led some linguists to argue for semantic selection (cf. Chomsky, 1986; Grimshaw, 1979) and others to argue for structured

selectional inheritance (Godard and Jayez, 1993). In fact, these perspectives are not that distant from one another (cf. Pustejovsky, 1995): in either view, there is an explicit lexical association between syntactic forms that is formally modeled by the grammar.

The second type of polysemy (syntactic alternations) involves verbal forms taking arguments in alternating constructions, the so-called '*verbal alternations*' (cf. Levin, 1993). These are true instances of polysemy because there is a logical (typically *causal*) relation between the two senses of the verb. As a result, the lexicon must either relate the senses through lexical rules (such as in head-driven phrase structure grammar (HPSG) treatments; cf. Pollard and Sag, 1994) or assume that there is one lexical form that has multiple syntactic realizations (cf. Pustejovsky and Busa, 1995).

(8a) The window opened suddenly.

(8b) Mary opened the window suddenly.

(9a) Bill began his lecture on time.

(9b) The lecture began on time.

(10a) The milk spilled onto the table.

(10b) Mary spilled the milk onto the table.

The final form of polysemy reviewed here is encountered mostly in nominals and has been termed '*regular polysemy*' (cf. Apresjan, 1973) and '*logical polysemy*' (cf. Pustejovsky, 1991) in the literature; it is illustrated in the following sentences:

(11a) Mary carried the book home.

(11b) Mary doesn't agree with the book.

(12a) Mary has her lunch in her backpack.

(12b) Lunch was longer today than it was yesterday.

(13a) The flight lasted 3 hours.

(13b) The flight landed on time in Los Angeles.

Notice that in each of the pairs, the same nominal form is assuming different semantic interpretations relative to its selective context. For example, in (11a) the noun *book* refers to a physical object, whereas in (11b) it refers to the informational content. In (12a), *lunch* refers to the physical manifestation of the food, whereas in (12b) it refers to the eating event. Finally, in (13a) *flight* refers to the flying event, whereas in (13b) it refers to the plane. This phenomenon of polysemy is one of the most challenging in the area and has stimulated much research (Bouillon, 1997; Bouillon and Busa, 2001). In order to understand how each of these cases of polysemy can be handled, we must first familiarize ourselves with the structure of individual lexical entries.

Lexical Relations

Another important aspect of lexical semantics is the study of how words are semantically related to one another. Four classes of lexical relations, in particular, are important to recognize: synonymy, antonymy, hyponymy, and meronymy.

Synonymy is generally taken to be a relation between words rather than concepts. One fairly standard definition states that two expressions are synonymous if substituting one for the other in all contexts does not change the truth value of the sentence where the substitution is made (cf. Cruse, 1986, 2004; Lyons, 1977). A somewhat weaker definition makes reference to the substitution relative to a specific context. For example, in the context of carpentry, *plank* and *board* might be considered synonyms, but not necessarily in other domains (cf. Miller *et al.*, 1990). The relation of antonymy is characterized in terms of semantic opposition and, like synonymy, is properly defined over pairs of lexical items rather than concepts. Examples of antonymy are *rise/fall*, *heavy/light*, *fast/slow*, and *long/short* (cf. Cruse, 1986; Miller, 1991). It is interesting to observe that co-occurrence data illustrate that synonyms do not necessarily share the same antonyms. For example, *rise* and *ascend* as well as *fall* and *descend* are similar in meaning, yet neither *fall/ascend* nor *rise/descend* are antonym pairs. For further details see Miller *et al.* (1990).

The most studied relation in the lexical semantic community is hyponymy, the taxonomic relationship between words, as defined in WordNet (Fellbaum, 1998) and other semantic networks. For example, specifying *car* as a hyponym of *vehicle* is equivalent to saying that *vehicle* is a superconcept of the concept *car* or that the set *car* is a subset of those individuals denoted by the set *vehicle*.

One of the most difficult lexical relations to define and treat formally is that of meronymy, the relation of parts to the whole. The relation is familiar from knowledge representation languages with predicates or slot-names such as 'part-of' and 'made-of.' For treatments of this relation in lexical semantics, see Miller *et al.* (1990) and Cruse (1986).

The Semantics of a Lexical Entry

It is generally assumed that there are four components to a lexical item: phonological, orthographic, syntactic, and semantic information. Here, we focus first on syntactic features and then on what semantic information must be encoded in an individual lexical entry.

There are two types of syntactic knowledge associated with a lexical item: its *category* and its *subcategory*. The former includes traditional classifications of

both the major categories, such as noun, verb, adjective, adverb, and preposition, as well as the minor categories, such as adverbs, conjunctions, quantifier elements, and determiners. Knowledge of the subcategory of a lexical item is typically information that differentiates categories into distinct, distributional classes. This sort of information may be usefully separated into two types, *contextual features* and *inherent features*. The former are features that may be defined in terms of the contexts in which a given lexical entry may occur. Subcategorization information marks the local syntactic context for a word. It is this information that ensures that the verb *devour*, for example, is always transitive in English, requiring a direct object; the lexical entry encodes this requirement with a subcategorization feature specifying that a noun phrase (NP) appear to its right. Another type of context encoding is collocational information, where patterns that are not fully productive in the grammar can be tagged. For example, the adjective *heavy* as applied to *drinker* and *smoker* is collocational and not freely productive in the language (Mel'čuk, 1988). '*Inherent features*' on the other hand, are properties of lexical entries that are not easily reduced to a contextual definition but, rather, refer to the ontological typing of an entity. These include such features as count/mass (e.g., *pebble* vs. *water*), abstract, animate, human, physical, and so on.

Lexical items can be systematically grouped according to their syntactic and semantic behavior in the language. For this reason, there have been two major traditions of word clustering, corresponding to this distinction. Broadly speaking, for those concerned mainly with grammatical behavior, the most salient aspect of a lexical item is its *argument structure*; for those focusing on a word's entailment properties, the most important aspect is its *semantic class*. In this section, these two approaches are examined and it is shown how their concerns can be integrated into a common lexical representation.

Lexical Semantic Classifications

Conventional approaches to lexicon design and lexicography have been relatively informal with regard to forming taxonomic structures for the word senses in the language. For example, the top concepts in WordNet (Miller *et al.*, 1990) illustrate how words are characterized by local clusterings of semantic properties. As with many ontologies, however, it is difficult to discern a coherent global structure for the resulting classification beyond a weak descriptive labeling of words into extensionally defined sets.

One of the most common ways to organize lexical knowledge is by means of type or feature inheritance mechanisms (Carpenter, 1992; Copestake and

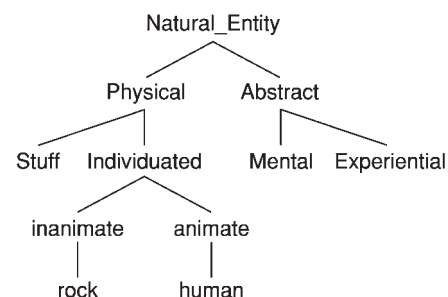

Figure 1 Type structures.

Briscoe, 1992; Evans and Gazdar, 1990; Pollard and Sag, 1994). Furthermore, Briscoe *et al.* (1993) described a rich system of types for allowing default mechanisms into lexical type descriptions. Similarly, type structures, such as that shown in **Figure 1**, can express the inheritance of syntactic and semantic features, as well as the relationship between syntactic classes and alternations (cf. Alsina, 1992; Davis, 1996; Koenig and Davis, 1999; Sanfilippo, 1993) and other relations (cf. Pustejovsky, 2001; Pustejovsky and Boguraev, 1993).

In the remainder of this section, we first examine the approach to characterizing the weak constraints imposed on a lexical item associated with its arguments. Then, we examine attempts to model lexical behavior by means of internal constraints imposed on the predicate. Finally, it is shown how, in some respects, these are very similar enterprises and both sets of constraints may be necessary to model lexical behavior.

Argument Structure

Once the base syntactic and semantic typing for a lexical item has been specified, its subcategorization and selectional information must be encoded in some form. There are two major techniques for representing this type of knowledge:

1. Associate 'named roles' with the arguments to the lexical item (Fillmore, 1985; Gruber, 1965; Jackendoff, 1972).
2. Associate a logical decomposition with the lexical item; meanings of arguments are determined by how the structural properties of the representation are interpreted (cf. Hale and Keyser, 1993; Jackendoff, 1983; Levin and Rappaport, 1995).

One influential way of encoding selectional behavior has been the theory of *thematic relations* (cf. Gruber, 1976; Jackendoff, 1972). Thematic relations are now generally defined as partial semantic functions of the event being denoted by the verb or noun, and they behave according to a predefined calculus of roles relations (e.g., Dowty, 1989). For example,

semantic roles such as agent, theme, and goal can be used to partially determine the meaning of a predicate when they are associated with the grammatical arguments to a verb.

- (14a) **put** <AGENT, THEME, LOCATION>
 (14b) **borrow** <RECIPIENT, THEME, SOURCE>

Thematic roles can be ordered relative to each other in terms of an implicational hierarchy. For example, there is considerable use of a universal subject hierarchy such as is shown in the following (cf. Comrie, 1981; Fillmore, 1968):

- (15) AGENT > RECIPIENT/BENEFACTIVE >
 THEME/PATIENT > INSTRUMENT >
 LOCATION>

Many linguists have questioned the general explanatory coverage of thematic roles, however, and have chosen alternative methods for capturing the generalizations they promised. Dowty (1991) suggested that theta-role generalizations are best captured by entailments associated with the predicate. A theta-role can then be seen as the set of predicate entailments that are properties of a particular argument to the verb. Characteristic entailments might be thought of as prototype roles, or proto-roles; this allows for degrees or shades of meaning associated with the arguments to a predicate. Others have opted for a more semantically neutral set of labels to assign to the parameters of a relation, whether it is realized as a verb, noun, or adjective. For example, the theory of argument structure as developed by Williams (1981), Grimshaw (1990), and others can be seen as a move toward a more minimalist description of semantic differentiation in the verb's list of parameters. The argument structure for a word can be seen as the simplest specification of its semantics, indicating the number and type of parameters associated with the lexical item as a predicate. For example, the verb *die* can be represented as a predicate taking one argument, *kill* as taking two arguments, where as the verb *give* takes three arguments:

- (16a) **die** (x)
 (16b) **kill** (x,y)
 (16c) **give** (x,y,z)

What originally began as the simple listing of the parameters or arguments associated with a predicate has developed into a sophisticated view of the way arguments are mapped onto syntactic expressions. Williams's (1981) distinction between *external* (the underlined arguments above) and *internal* arguments and Grimshaw's proposal for a hierarchically structured representation (cf. Grimshaw, 1990) provide us with the basic syntax for one aspect of a word's

meaning. Similar remarks hold for the argument list structure in HPSG (Pollard and Sag, 1994) and Lexical Functional Grammar (Bresnan, 1994).

The interaction of a structured argument list and a rich system of types, such as that presented previously, provides a mechanism for semantic selection through inheritance. Consider, for instance, the sentence pairs in (17):

- (17a) The man/the rock fell.
 (17b) The man/*the rock died.

Now consider how the selectional distinction for a feature such as animacy is modeled so as to explain the selectional constraints of predicates. For the purpose of illustration, the arguments of a verb will be identified as being typed from the system shown previously.

- (18a) λx : physical[**fall**(x)]
 (18b) λx : animate[**die**(x)]

In the sentences in (17), it is clear how rocks cannot die and men can, but it is still not obvious how this judgment is computed, given what we would assume are the types associated with the nouns *rock* and *man*, respectively. What accomplishes this computation is a rule of subtyping, Θ , that allows the type associated with the noun *man* (i.e., 'human') to also be accepted as the type 'animate,' which is what the predicate *die* requires of its argument as stated in (18b) (cf. Carpenter, 1992).

- (19) Θ [*human* \sqsubseteq *animate*]: *human* \rightarrow *animate*

The rule Θ , applies since the concept 'human' is subtyped under 'animate' in the type hierarchy. Parallel considerations rule out the noun *rock* as a legitimate argument to *die* since it is not subtyped under 'animate.' Hence, one of the concerns given previously for how syntactic processes can systematically keep track of which 'selectional features' are entailed and which are not is partially addressed by such lattice traversal rules as the one presented here.

Event Structure and Lexical Decomposition

The second approach to lexical specification mentioned previously is to define constraints internally to the predicate. Traditionally, this has been known as 'lexical decomposition.' In this section, we review the motivations for decomposition in linguistic theory and the proposals for encoding lexical knowledge as structured objects. We then relate this to the way in which verbs can be decomposed in terms of eventualities (Tenny and Pustejovsky, 2000).

Since the 1960s, lexical semanticists have attempted to formally model the semantic relations between

lexical items such as between the adjective *dead* and the verbs *die* and *kill* (cf. Lakoff, 1965; McCawley, 1968) in the following sentences:

- (20a) John killed Bill.
- (20b) Bill died.
- (20c) Bill is dead.

Assuming the underlying form for a verb such as *kill* directly encodes the stative predicate in (20c) and the relation of causation, generative semanticists posited representations such as (21):

- (21) (CAUSE (x , (BECOME (NOT (ALIVE y))))

Here the predicate CAUSE is represented as a relation between an individual causer x and an expression involving a change of state in the argument y . Carter (1976) proposes a representation quite similar, shown here for the causative verb *darken*:

- (22) (x CAUSE ((y BE DARK) CHANGE))

Although there is an intuition that the cause relation involves a causer and an event, neither Lakoff nor Carter make this commitment explicitly. In fact, it has taken several decades for Davidson's (1967) observations regarding the role of events in the determination of verb meaning to find their way convincingly into the major linguistic frameworks. A new synthesis has emerged that attempts to model verb meanings as complex predicative structures with rich event structures (cf. Hale and Keyser, 1993; Parsons, 1990; Pustejovsky, 1991). This research has developed the idea that the meaning of a verb can be analyzed into a structured representation of the event that the verb designates, and it has furthermore contributed to the realization that verbs may have complex, internal event structures. Recent work has converged on the view that complex events are structured into an inner and an outer event, where the outer event is associated with causation and agency, and the inner event is associated with telicity (completion) and change of state (cf. Tenny and Pustejovsky, 2000).

Jackendoff (1990) developed an extensive system of what he calls '*conceptual representations*,' which parallel the syntactic representations of sentences of natural language. These employ a set of canonical predicates, including CAUSE, GO, TO, and ON, and canonical elements, including Thing, Path, and Event. These approaches represent verb meaning by decomposing the predicate into more basic predicates. This work owes obvious debt to the innovative work within generative semantics, as illustrated by McCawley's (1968) analysis of the verb *kill*. Recent versions of lexical representations inspired by

generative semantics can be seen in the lexical relational structures of Hale and Keyser (1993), where syntactic tree structures are employed to capture the same elements of causation and change of state as in the representations of Carter, Levin and Rapoport, Jackendoff, and Dowty. The work of Levin and Rappaport, building on Jackendoff's lexical conceptual structures, has been influential in further articulating the internal structure of verb meanings (Levin and Rappaport, 1995).

Pustejovsky (1991) extended the decompositional approach presented in Dowty (1979) by explicitly reifying the events and subevents in the predicative expressions. Unlike Dowty's treatment of lexical semantics, where the decompositional calculus builds on propositional or predicative units (as discussed previously) a 'syntax of event structure' makes explicit reference to quantified events as part of the word meaning. Pustejovsky further introduced a tree structure to represent the temporal ordering and dominance constraints on an event and its subevents. For example, a predicate such as *build* is associated with a complex event such as the following (cf. also Moens and Steedman, 1988):

- (23) [*transition*[e_1 :PROCESS] [e_2 :STATE]]

The process consists of the building activity itself, whereas the state represents the result of there being the object built. Grimshaw (1990) adopted this theory in her work on argument structure, where complex events such as *break* are given a similar representation. In such structures, the process consists of what x does to cause the breaking, and the state is the resultant state of the broken item. The process corresponds to the outer causing event as discussed previously, and the state corresponds in part to the inner change of state event. Both Pustejovsky and Grimshaw differ from the previous authors in assuming a specific level of representation for event structure, distinct from the representation of other lexical properties. Furthermore, they follow Higginbotham (1985) in adopting an explicit reference to the event place in the verbal semantics.

Rappaport and Levin (2001) adopted a large component of the event structure model for their analysis of the resultative construction in English. Event decomposition has also been employed for properties of adjectival selection, the interpretation of compounds, and stage and individual-level predication.

Qualia Structure

Thus far, we have focused on the lexical semantics of verb entries. All of the major categories, however,

are encoded with syntactic and semantic feature structures that determine their constructional behavior and subsequent meaning at logical form. In generative lexicon theory (Pustejovsky, 1995), it is assumed that word meaning is structured on the basis of four generative factors, or ‘*qualia roles*’, that capture how humans understand objects and relations in the world and provide the minimal explanation for the linguistic behavior of lexical items (these are inspired in large part by Moravcsik’s (1975, 1990) interpretation of Aristotelian *aitia*). These are the formal role, the basic category that distinguishes the object within a larger domain; the constitutive role, the relation between an object and its constituent parts; the telic role, its purpose and function; and the agentive role, factors involved in the object’s origin or ‘coming into being.’ Qualia structure is at the core of the generative properties of the lexicon since it provides a general strategy for creating new types. For example, consider the properties of nouns such as *rock* and *chair*. These nouns can be distinguished on the basis of semantic criteria that classify them in terms of general categories such as *natural_kind*, *artifact_object*. Although very useful, this is not sufficient to discriminate semantic types in a way that also accounts for their grammatical behavior. A crucial distinction between *rock* and *chair* concerns the properties that differentiate *natural_kinds* from *artifacts*: Functionality plays a crucial role in the process of individuation of artifacts but not of natural kinds. This is reflected in grammatical behavior, whereby ‘a good chair’ or ‘enjoy the chair’ are well-formed expressions reflecting the specific purpose for which an artifact is designed, but ‘good rock’ or ‘enjoy a rock’ are semantically ill formed since for *rock* the functionality (i.e., telic) is undefined. Exceptions exist when new concepts are referred to, such as when the object is construed relative to a specific activity, as in ‘The climber enjoyed that rock’; *rock* takes on a new meaning by virtue of having telicity associated with it, and this is accomplished by integration with the semantics of the subject NP. Although *chair* and *rock* are both *physical_object*, they differ in their mode of coming into being (i.e., agentive): artifacts are man-made, *rocks* develop in nature. Similarly, a concept such as *food* or *cookie* has a physical manifestation or denotation, but also a functional grounding, pertaining to the relation of ‘eating.’ These apparently contradictory aspects of a category are orthogonally represented by the qualia structure for that concept, which provides a coherent structuring for different dimensions of meaning.

Limits of Language

G Priest, University of Melbourne, Melbourne, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

One thing that language (to the sense of which notion we will return in a moment) obviously does well is express things. In particular, it can be used to express information, often of a very complex kind. It might therefore be wondered whether there are limits to this: is there any kind of information that cannot be expressed in language (Alston, 1956)? It is not uncommon to hear it said that there is of course such information: one cannot express the taste of a peach, or the color red. But obviously one *can* express such things. The color red is – what else? – red. What is usually meant by inexpressibility claims, say, about redness, is that there is nothing that can be said in words that will conjure up the mental image of red for someone who has never experienced this before. Maybe so. But to identify meaning with such images, though a natural enough view, is hardly tenable. As the 20th-century Austrian philosopher Ludwig Wittgenstein pointed out in the *Philosophical investigations* (Wittgenstein, 1953), there are many words and phrases that conjure up no such images; and if a person is able to use a word correctly in the company of others, what mental images they are experiencing, if, indeed, any at all, is quite immaterial. Their words are meaningful, and so convey their information, in the usual way. (Private images are irrelevant to public meaning.)

It is sometimes claimed that representations such as pictures, maps, and diagrams can convey information that cannot be captured verbally. No doubt they can often express information more effectively, but it is hard to find examples of information expressible only in this way (especially once one has jettisoned the view that mental imagery has any intrinsic connection with meaning). And, in any case, it is natural enough to think of representations of this kind as languages. It seems profitless (to me, anyway) to dispute over whether or not such things *really* are a language. They share with verbal language at least this: they are structured forms of representation that can be used to convey information of a kind that may never have been expressed before. If, therefore, we are looking for information that cannot be represented, we will have to look elsewhere.

It is presumably uncontentious that relative to most – maybe all – systems of representations there will be information that cannot be expressed. Thus, a medieval monk did not have the conceptual resources

to speak about microchips and quantum fields. It can still, of course, be represented by some other system – maybe the old one augmented by the appropriate concepts. Similarly, relative to any abstract system of representations, there are likely to be things that can be represented, but that, because of their computational complexity, outstrip the resources available to a human brain, and so are inaccessible. These things could become accessible with the help of a different form of representation, however. (Thus, the multiplication of numbers using Roman numerals is computationally much harder than multiplication using Arabic numerals.) The interesting question is whether there is information that is not just unrepresentable because of contingent constraints of this kind but whether there is information that is essentially so. If there is, it is unlikely that this will be demonstrable without appeal to some substantial metaphysical views.

One such view concerns the nature of God. In certain kinds of Christian theology, God is taken to be so different in kind from anything that humans can conceive of that no human concepts can be correctly applied to Him. Because all language deploys only such concepts, the true nature of God cannot be expressed in language (Alston, 1998).

The claim that the nature of God is ineffable is sometimes buttressed by other considerations, especially in the Neo-Platonist tradition. God, it is claimed, is the ground of all beings. That is, He is that which creates and sustains all beings. As such, He is not Himself a being: not a *this* rather than a *that*. His nature cannot, therefore, be communicated in words: to say anything about Him would be to say that He is a *this*, rather than a *that*, and so treat Him simply as another being.

The thought that beings have a ground of this kind is not restricted to Christianity but seems to be a perennial one. It is found in Neo-Platonism (Christian and non-Christian), in which the One plays this role (O'Meara, 1993); it is found in Hinduism, in which Brahman plays this role; it is found in Taoism, in which the Tao plays this role (Lau, 1982); it is found in the writings of the 20th-century German philosopher Martin Heidegger, in which Being (*Sein*) plays this role (Krell, 1977).

A closely related, but different, view is that there is a fundamental or ultimate reality such that the reality that we perceive or conceive is obtained by the imposition of a conceptual grid thereupon. To say what it is like, in itself, is therefore impossible, as anything said about it will deploy our conceptual grid, which is simply a superposition. Again, the existence of such

a reality seems a perennial thought. It is the role played by chora ($\chi\omega\rho\alpha$) in Plato's *Timaeus*; it is the role played by ultimate reality (emptiness, *sūnyatā*) in various branches of Mahayana Buddhism, especially Yogacara (Williams, 1998). Indeed, when Taoism and Indian Mahayana fused to give Chan (Zen), this theme merged with the previous one. Fundamental reality (Buddha nature) can be appreciated only via a direct experience. It is a simple 'thusness' or 'suchness,' beyond all words (Kasulis, 1989).

In some ways, the views of the 18th-century German philosopher Immanuel Kant, as expressed in his *Critique of pure reason* (Kemp Smith, 1923) are similar. For Kant, the empirical world is not independent of us but is partly constituted by our mental concepts. These include the forms of space and time. More particularly for present concerns, these include the logical categories that we apply when we make judgments (such as *all/some, is/is not*). These categories, moreover, depend for their applicability on temporal criteria. Reason forces us, however, to think (about) reality as it is in itself, independent of our mental constructions 'things in themselves' (*dinge an sich*). And because such things are outside time, there is no way that we can apply our categories to them, and so make judgments about them. Thus, although we are forced to recognize the existence of such a reality, there is nothing that can be said about it.

About a century and a half later, but for quite different reasons, Wittgenstein ended up in a similar situation when he wrote the *Tractatus logico-philosophicus* (Pears and McGuinness, 1961). For Wittgenstein, reality is constituted by certain states of affairs; these are composed of objects configured in certain ways. Language, on the other side of the fence, is constituted by propositions; these are composed of names configured in certain ways. A proposition represents a state of affairs if the names in it correspond to the objects in the state, and the configuration of names in the proposition is isomorphic to (has the same form as) the configuration of objects in the state. (This is the so-called picture theory. Wittgenstein is reputed to have been provoked into it by noting how the icons in a scale-representation work.)

It is a consequence of this view that any situation that is not a configuration of objects cannot be expressed in a proposition. Indeed, attempts to do so will produce semantic nonsense. Such situations cannot, therefore, be described. An irony of this is that Wittgenstein's theory itself requires him to talk, not just of objects but also of propositions, configurations, form; and for various reasons these cannot be objects. (For example, propositions can be asserted or denied; objects cannot. And the form of a state of

affairs is not one of the objects in it: it is the way that those objects are structured together.) His own theory is therefore an attempt to do the impossible. This triggers the spectacular dénouement to the *Tractatus*, in which Wittgenstein pronounces his own theory to be nonsense.

The final considerations that I will mention that drive toward things inexpressible concern the infinite, as it is understood in modern logic and mathematics (Moore, 1985). According to this, there are different sizes of infinity. The smallest of these, *countable infinity*, is the size of the natural numbers (0, 1, 2, ...). Because the totality of objects (or even of numbers) is larger than this, so will be the totality of facts about them. (For each object, for example, it is either finite or infinite.) But any language (at least of the kind that is humanly usable) can be shown to have only countably many sentences. There will therefore be many facts that cannot be expressed.

Of course, for all that this shows, each of these facts could be expressed by some richer language; for example, one obtained by adding another name. But there is more to it than this. To say something about an object, one has to refer to it; to do this, one has to be able to single it out in some way; and the totality of all objects is so rich that it will contain objects that are entirely indiscriminable from each other by our finite cognitive resources, and so that cannot be singled out. (Points in a continuum, for example, may be so close as to be indistinguishable by any cognitive mechanism.) There is much, therefore, that will be inexpressible.

As we have now seen, there is a wide variety of metaphysical views that deliver the conclusion that there are things that are ineffable. Evaluating these views goes well beyond anything possible here. I will conclude with a brief discussion of a structural feature of (discussions of) the ineffable.

As is probably clear, theories that claim that certain things are inexpressible have a tendency to say just such things. Thus, Christians say much about God, Buddhists say much about emptiness, Heidegger says much about Being, Kant says much about *dinge an sich*, and Wittgenstein says much about the relation between language and reality. What is one to say about this?

The only thing one can say is that these claims are either literally false or meaningless. The second move is made by Wittgenstein in the *Tractatus*. The first move is more common: all one can do is *deny* any claim made about the object in question. One finds this move in Christian negative theology (Braine, 1998) and some versions of Hinduism, for example, the Advaita Vedānta of Śāṅkara (Sengaku Mayeda, 1992). Kant struggles with a version of this

view when he distinguishes between a legitimate negative notion of *ding an sich* and an illegitimate positive one.

This cannot be the whole story, however, as each position does appear to endorse various claims about the ineffable. How are these to be understood? The most common move is to suggest that one has to understand such assertions as metaphorical, analogical, or in some other nonliteral way. So understood, they can 'point to' the ineffable, although not express it. In Christian theology, this move is made by the 11th-century theologian St. Anselm; similar claims also can be found in the Zen tradition; and Heidegger uses the notion of writing under erasure ('~~x~~') in an attempt to indicate that his words are not to be taken literally.

There is something very unsatisfactory about this, though. One thing that each tradition gives is a set of reasons as to why the thing in question cannot be described: God is beyond categorization; the ground of being is not itself a being; ultimate reality has no features; categories cannot be applied to things outside time; propositions and form are not objects. If one does not understand these claims as literally true, then the very ground for supposing the things in question to be inexpressible falls away. (If 'Juliet is the sun' is not to be taken literally, there is no reason to suppose that she is made of hydrogen and helium.)

Indeed, at the very heart of the view that language has limits is a fundamental paradox (Priest, 1995). To claim that language has limits is to claim that there are things that cannot be talked about; but to say this is exactly to talk about them. The paradox manifests itself in a precise form in some of the paradoxes of self-reference in modern logic. There are many ordinal numbers that cannot be referred to. So there is a least such. But 'the least number that cannot be referred to' refers to that number – Köning's paradox. For skeptics about sizes of infinity, there is even a finite version of this. There is only a finite number of names (i.e., proper names or definite descriptions) with less than (say) 100 letters (in English); there is therefore a finite number of (natural) numbers that can be referred to by names of this kind. So there will be numbers that cannot be referred to in this way. 'The least number that cannot be referred to with less

than 100 letters' (which has less than 100 letters) refers to one of these – Berry's paradox. Various responses to these paradoxes have been proposed in modern logic, but none that is either generally accepted or unproblematic.

One reaction to the fundamental paradox is to reject the notion of the limits of language altogether: there is nothing that it is beyond the ability of language to express. But any theory according to which there are limits to language – including, it would seem, contemporary logic – would appear to be stuck with this contradiction.

Linguistic Reality

L Wetzel, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Linguistic reality is that portion or aspect of reality that linguistics seeks to understand and explain, and in virtue of which true linguistic claims are true. Linguistics is the scientific study of language, its units, nature, and structure. To see what the units, nature, and structure of language are, we should look to what linguists say. A reasonable place to begin is *An encyclopedia of language*. It reveals that in addition to languages and language users, phonetics cuts up linguistic reality into vowels, consonants, syllables, words, and sound segments, the human vocal tract and its parts (the tongue has five), among other things. Phonology is also concerned with sounds, but organizes them in terms of phonemes, allophones, alternations, utterances, phonological representations, underlying forms, syllables, words, stress-groups, feet, and tone groups. In grammar, morphology describes morphemes, roots, affixes, and so forth, and syntax analyzes sentences, semantic representations, LF representations, among other things. Semantics studies signs, their meanings, their sense relations, propositions, etc. Pragmatics deals with speech acts, speaker meanings, sentence meanings, implicatures, presuppositions, etc. Lexicography investigates nouns, verbs, words, their stems, definitions, forms, pronunciations, origin.

Why Those Objects?

What is the linguist's justification for positing, or recognizing, vowels and consonants, phonemes, morphemes, words, sentences and so on? A general though unhelpful answer is that countenancing such objects produces theories that have a great deal of classificatory, explanatory, and predictive power. The more specific question 'but why posit phonemes?' must be justified within phonology by comparing a theory with phonemes to one without, as must the more specific question of why [b] and [p] are phonemes of English. Why certain noises are enshrined as dictionary entries needs to be justified within lexicographical methodology, rather than, say, within philosophy. The point is that the justification is to be found within linguistic theory, and in most cases within a particular subdiscipline, since subdisciplines have different assumptions. (Phonetics and phonology approach the sound signal differently and hence parse it in terms of different units. Lexicography

might give credence to the thesis that all linguistic objects have instances, since each of the million or so words recognized by the *O.E.D.* have been uttered or inscribed by someone at some time. But grammar might not; there are more, perhaps infinitely many more, sentences than will ever be used.) Assuming there is sufficient internal justification for recognizing the existence of the above-mentioned objects, we may now ask the following question.

What Are They?

What, for example, is that quintessential linguistic object an expression? For that matter, what is a language? One answer to the former would be that an expression is anything that is a noun, verb, adjective, etc., or a sequence of such things built up by means of the grammatical rules. But that merely raises the question of what these other things are. Obviously, nouns and verbs are for the most part **words**, but what are words? Are they physical objects, particular events, abstract objects, kinds, classes, or mental entities? (Parallel questions may be asked of languages: are they social practices, abstract objects, classes of expressions, or psychological products of the language faculty? While it is beyond the scope of this short encyclopedia article to address the more complicated question about language, it is worth noting that the proposed answers mirror those given below on what a word is.)

Types and Tokens

Before such questions can be tackled, we have to disambiguate the word 'word,' which could mean either 'word type' or 'word token.' There is only one definite article in English, the word 'the' – the word type – but there are millions of the's on pages in the Library of Congress and the lips of members of Congress – the word tokens (*see Type versus Token*). Word tokens are particulars; they might be composed of ink, sounds, or smoke signals. They have a unique spatiotemporal location, unlike types. Types are unique but capable of more than one instantiation or representation, unlike their tokens. A good indicator that there are both types and tokens is the different counting procedures associated with the same word. When it is said that an educated person's vocabulary is upward of 10 000 words, that there are exactly 26 letters of the English alphabet, or that English has 18 cardinal vowels, types are being counted, since the numbers would exceed a million if we were counting tokens. As the examples suggest, not only words but

also vowels, phonemes, letters, utterances, sentences, and most of the rest of the linguistic objects found in our survey come in types and tokens.

Which sorts of objects, then, does linguistics explicitly refer to and quantify over – types or tokens? Types – although linguistics is an empirical science based on empirical data, applicable to particulars – tokens – in the causal realm. Yet to ensure generality in an economical format, most of the references and quantifications that appear in linguistic theory involve types and their relationships to each other. Expressions, for example, may be composed of words, and words composed of syllables, and syllables of phonemes, and phonemes of features – all of which are types. (This might be thought puzzling; how can an expression such as ‘Pease porridge hot, pease porridge cold’ be six words long, if there are only four words, each of them unique, of which it might be composed? For a resolution of this puzzle, (see **Type versus Token**). Linguistics, in other words, is awash in references to and quantifications over types, including words. Our original question then becomes the following one.

What Are Word Types?

It should be clear that word types (hereafter: words) are not particular physical objects/events, but it remains to be seen whether they are abstract objects, kinds, classes, or mental entities – or perhaps whether they do not exist at all.

Even among word types, there are several sorts of words. Yet one of the lexicographer’s uses of the word ‘word’ stands out. A rough characterization of this sort is *the sort of thing that merits a dictionary entry*. (*Rough*, because some entries in the dictionary, e.g., *il-*, *-ile*, and *metric system* are not words, and some words, e.g., place names and other proper names, do not get a dictionary entry.) To fix our thoughts on what an account must explain, let us consider the word *color*, or *colour*. According to the *O.E.D.*, the noun *color* is from early modern English, is pronounced [kʌlər] has two ‘modern current or most usual spellings’ [colour, color]; 18 earlier spellings [collor, collour, coloure, colowr colowre, color colure, cooler, couler, coullor, coullour, coolore, coulor, coulure, coulour, culler, cullor, cullour]; and 18 different senses – divided into four branches – with numerous subsenses. The verb *color* is a different word, but with the same pronunciation and spellings (*O.E.D.*, vol. 2: 636–639). *Webster’s* assures us that the word *schedule* has four current pronunciations: [ˈske-(,)jü(ə)l], [ˈske-jəl] (US), [ˈshe-jəl] (Can.) and [ˈshe-(,)dyü(ə)l] (Eng.) (*O.E.D.*, vol. 2: 1044). Thus, a word can be written or spoken; it can have more

than one correct spelling, more than one correct spelling at the same time, more than one sense at the same time, the same correct spelling and pronunciation as a different word; and lastly, a word may have more than one correct pronunciation at a given time. These linguistic facts have to be accommodated by any account of words.

Realism

Probably the most popular account of words is given by platonic realism: words are abstract objects – acausal objects, like numbers, that have no spatio-temporal location. As can be seen from the preceding paragraph, they are very abstract entities indeed, for there is no relatively simple property, like spelling or pronunciation or meaning, that all tokens of the word *color* have in common; not even all their written tokens have the same correct spelling. (Indeed, the realist may argue that that is one of the primary justifications for positing word types – being a token of the word *color* might be the only glue that binds the considerable variety of space-time particulars together). This should discourage the misconception that realism is committed to a platonic ‘form’ (the spelling, say) that all instances resemble the way a cookie resembles a cookie cutter (although the old view lives on in the fact that spellings are called ‘forms’ of the word). Family resemblance in the standard cases is the most that might be hoped for, but intentionality and context are such important factors in determining what type a token is a type of, that even resemblance can fail in nonstandard cases. (It should be noted, if it is not already clear from the foregoing, that a physical object that is a token of a type is not one **intrinsically** – merely by being a certain sequence of shaped ink marks, say. It is only a token relative to a type, a language, and perhaps an orientation. Moreover, it may need to have been produced with a certain intention and in accordance with certain conventions.)

Platonic realism, whether of words or any other abstract objects, must face a serious epistemological challenge, namely, to explain how it is that spatio-temporal creatures such as ourselves can have knowledge of these abstract things if we cannot causally interact with them. Admittedly, we do causally interact with word tokens, but if the tokens are as diverse as was emphasized above, how do we arrive at the properties of the type at all? There are various realist responses to this problem (responses that are not necessarily mutually exclusive). One is to appeal to intuition. Another is to claim that just as maps represent a city, so tokens represent their types, thus reducing the problem to one of characterizing

representation. Another is to reject platonic realism altogether in favor of Aristotelian realism. This involves dropping the claim that words have no spatiotemporal location, and claiming instead that they have many such locations; each type is 'in' each of its tokens. Such a position suggests that there could not be an uninstantiated type. While plausible for words, it is not plausible for sentences. A third response is to claim that words are kinds, just as species are, thus reducing the problem of how we arrive at knowledge of types to one of induction.

Conceptualism

As the terms 'platonic' and 'Aristotelian realism' suggest, we have run into the old philosophical problem of universals in virtue of the fact that types have instances. Not surprisingly, the same camps are in evidence here. The traditional opponents of universals/abstract objects were the conceptualists and the nominalists. The conceptualists argued that there are no general things such as *man*; there are only general *ideas* – that is, ideas that apply to more than one thing. Applied to words, the thesis would be that words are not abstract objects 'out there,' but objects in the mind. Their existence then, would be contingent on having been thought of. While this contingency may have a good deal to recommend it in the case of linguistic items, by itself conceptualism is just a stop-gap measure. For ideas also appear to come in types and tokens (as evidenced by the fact that two people sometimes have the same idea). So either the conceptualist is proposing that word types are idea types – which would be a species of realism – or she is proposing that there are no types, only mental particulars in particular persons, which is a species of nominalism.

Nominalism

The problem for those hostile to universals and abstract objects is to account for our apparent theoretical commitment to types, which are clearly not spatiotemporal particulars. Traditional nominalists argued (as their name implies) that there are no general things, there are only general words, which apply to more than one thing. But this too is not a solution to the current problem, presupposing as it does that there are word types – types are the problem.

Class nominalists have proposed that a word type is just the class, or set, of its tokens. But this is unsatisfactory because, first, classes are abstract objects too, so it is hard to see how this is really a form of nominalism about abstract objects. And second, classes are ill-suited for the job, since classes have

their membership and their cardinality necessarily, but how many tokens a word has is a contingent matter. (One less token would not annihilate the word.)

Initially more promising is the nominalistic claim that talk of types is harmless because it is unnecessary – it is just shorthand for talk of tokens. *The mountain lion is a mammal* is easily translated as 'every mountain lion is a mammal.' So to refer to the noun *color*, say, we need only refer instead to all its tokens. One problem is how to do this. We can't say 'every token of the noun "color"...,' because 'color' refers to a type. And 'every noun "color"...' does not seem grammatical, a fact that is even more apparent if we consider sentences (e.g., 'every "the cat is on the mat"...'). Even if we could, truths will convert to falsehoods (using the 'every'-conversion). The noun *color* is pronounced [kɒ'lər], but particular inscriptions of it are not audible at all. So the question is how we might identify these tokens grammatically but without referring to the noun *color* itself and still say something true and (in some appropriate sense) equivalent. The idea seems to be that the type must embody certain similar features that all and only its tokens have. This is a beguiling idea, until one tries to find such a feature, or features, amid the large variety of its tokens – even the well-formed tokens. Consider *color* and *schedule* again. They demonstrate that neither same spelling, same sense, nor same pronunciation prevail. As the preeminent nominalist Goodman observed, "Similarity, ever ready to solve philosophical problems and overcome obstacles, is a pretender, an impostor, a quack Similarity does not pick out inscriptions that are 'tokens of a common type' Only our addiction to similarity deludes us into accepting similarity as the basis for grouping inscriptions into the several letters, words, and so forth" (Goodman, 1972: 437–438).

Further undermining the reductive approach being considered is that each of the possible defining features mentioned (e.g., spelling, pronunciation) involve reference to types: letter types in the spellings, phoneme types in the pronunciation. (Types are defined in terms of each other.) These too would have to be analyzed away in terms of quantifications over particulars. If, as a last resort, one were to specify a massive disjunction that avoided all references to types, one that captured each and every token of the noun *color*, one would capture tokens of other words, too. Paraphrasing quantifications over word types would be extraordinarily difficult. The moral is that whatever word types are, they are indispensable.

Linguistics as a Science

B Clark, Middlesex University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A common description of linguistics is that it is the 'scientific study of language.' This might seem to be a loose or metaphorical use since the subject matter of linguistics is quite different from what are often thought of as the 'hard' sciences such as physics or chemistry. But linguists are engaged in a process of inquiry that aims to discover facts about the world we live in, and so their work shares important properties of other sciences. Some work in linguistics (e.g., acoustic phonetics) resembles the 'hard' sciences in that it studies physical phenomena in the world. Like psychology, linguistics faces specific issues associated with the fact that its subject matter involves properties of humans, namely, linguistic knowledge and behavior. This article considers some views on what it means to say that a discipline is scientific, what it means to investigate language scientifically, and some different scientific approaches adopted by linguists.

What Is a Science?

The general, popular assumption about what constitutes a science is still probably one based on 'inductivism,' or logical positivism, which was the dominant view of science at the start of the 20th century. In this view, scientists must begin by making sure that they are as objective as possible and simply observe relevant data without prejudging it. They must also make every effort to ensure that they do not themselves affect the data that they are studying. After objectively observing the data, generalizations will emerge and from these generalizations, laws can be derived.

Suppose, for example, that we go to the Antarctic and observe penguins. After a certain number of observations, we might notice that we have never seen a penguin fly. On the other hand, we have seen many penguins swim. So we wonder whether these facts might be the basis of generalizations. We continue to observe and every penguin we observe swims but none of them fly, so we do generalize and come up with the hypotheses that:

- (1) No penguins can fly
- (2) All penguins can swim

These hypotheses can then be tested by further observation. We might also devise specific tests. For example, we might encourage penguins into the air to see whether any of them attempt to fly. Or we might put penguins in water to make sure each of them can swim. Hypotheses (1) and (2) will hold as long as every penguin we observe swims but fails to fly. If repeated tests confirm the hypotheses, then they will be established as verified conclusions.

This approach seems intuitive and clear to most people, but there are serious problems with it. Adapting a diagram from Chalmers (1999: 54), we can represent this way of approaching science as in **Figure 1**.

Perhaps the most fundamental problem with this model is that the derivation of laws and theories is based on induction, which means that they can never be guaranteed to be true. To see this, we need to look at what is involved in induction.

Induction is a process whereby general conclusions are derived based on evidence provided by specific observations in the past. If I go to the same bar often enough and order the same drink, say, a pint of stout, every time, it is possible that the bartender will conclude that I will want a pint of stout every time I come into the bar. If he is keen to make sure I am happy, he might even start pouring my stout as soon as he sees me arrive.

The problem, of course, is that there is nothing to stop me deciding one day to have something different for a change. If I do order a different drink one day, say a glass of lemonade, then the bartender will have wasted his time, and possibly his stout. In other words, conclusions that have been derived through a process of induction are not secure. By contrast, deductive conclusions are guaranteed to be true as long as the premises on which they are based are true. Here are possible steps in the bartender's inductive reasoning process:

- (3a) Billy ordered a pint of stout when he came into the bar on Monday.
- (3b) Billy ordered a pint of stout when he came into the bar on Tuesday.

- (3c) Billy ordered a pint of stout when he came into the bar on Wednesday.
- (3d) Therefore, Billy will order a pint of stout every time he comes into the bar.

And here are two examples of deductive inferences:

- (4a) Billy will order a pint of stout every time he comes into the bar.
- (4b) Therefore, Billy will order a pint of stout when he comes into the bar on Thursday.
- (5a) Billy is drinking stout
- (5b) All stouts are alcoholic drinks.
- (5c) Therefore, Billy is drinking an alcoholic drink.

While (3a–c) could be true and (3d) still turn out to be false, there is no way that (4a) could be true and (4b) false, or that (5a–b) could be true and (5c) false.

The unreliability of inductive inferences is a serious problem for the inductivist approach to science, since it means that no conclusion can ever be safely asserted to be true. You never know for sure that the next penguin you look at won't be able to fly, or whether the next penguin you look at will indeed be able to swim. This means not only that we can't be sure of our conclusions but also that we can never be sure that our scientific endeavors have resulted in any progress. It is always possible that we have just moved from one false hypothesis to another, since we have not been lucky enough to come across the data that would demonstrate our mistake.

Another problem with this view of scientific inquiry is that it is not possible to observe phenomena objectively without first making some assumptions about what might be relevant. Suppose, for example, that I decide I am interested in how children acquire their first language. How will I know which things to observe? Should I begin by observing the speech of the children themselves? Or the speech of other children around them? Or the speech of grownups around them? Or other kinds of behavior exhibited by the children themselves? Or other kinds of behavior exhibited by other children? Or other kinds of behavior exhibited by grownups around them? Or the extent to which they see or hear television? Or their diet? There are countless possibilities and we cannot begin carefully observing data without first guessing which particular data might be relevant. In the same way, hypotheses about whether penguins can fly or swim arise because someone asks the question whether they can. A scientist following the inductivist model might just as easily have decided to look at the penguins' color, their physical behavior, how they mate, how many of them are ever together in one group, and so on. The hypotheses about their status as flightless swimmers will only arise if it is assumed that it might be relevant in this context.

Figure 1 Inductivist model of science (based on Chalmers, 1999: 54).

Not only does the inductivist model of science mean we can never be sure we've made any progress, we also don't have any clear rationale for deciding on our first steps in investigating a particular phenomenon.

These were acknowledged problems for the traditional, inductivist model of science. But no superior model was available until the philosopher Karl Popper (1972, 1979) suggested a new way of thinking about science. He pointed out that, even though we can never be sure an assumption is true, we can demonstrate a conclusion to be false. If I order a glass of lemonade even once, then we know that it's not true that I only ever order stout. If we see just one penguin that can fly, then we know for certain that not all penguins are flightless. He pointed out that falsifying a hypothesis counts as progress, not only because it removes an error from a theory but also because it usually leads to a new, improved hypothesis. Suppose, for example, that we discover a flying penguin. We will not simply reject our initial hypothesis that all penguins are flightless and start again from scratch. Instead, we will wonder what the difference is between those penguins that fly and those that don't. We might, for example, discover that there is a particular penguin species that can fly and come up with a new hypothesis to reflect that.

Another important point Popper made was that the source of hypotheses is much less important than whether they make clear predictions and so can be tested to see if they are false. Newton's theory of gravity, for example, clearly predicts that any object we drop will fall towards the earth. Other things being equal, we know that a floating or rising object will demonstrate that the hypothesis is false. By contrast, if your horoscope claims that 'someone is thinking of you,' it is clearly impossible to show that this is not so. Therefore, this is not a falsifiable, and so not a scientific, claim.

Popper's approach suggests that observation does not need to be the first step in a process of scientific inquiry. Instead, hypotheses can, and indeed must, precede observation. Hypotheses may arise because of objective observation, because of some subjective prejudice, because we dream them, or from any source at all. What is important is that we can test them and so attempt to make progress in our understanding. Popper's view of how science progresses can be represented diagrammatically, as in Figure 2.

The foundations of science, in this view, are not based on objectivity and the notion that observation precedes hypothesis formulation. Instead, what is important is that our hypotheses are clearly formulated and testable. Since we can never verify a hypothesis, we aim instead to develop the best hypotheses we can, and this is evaluated in terms of clarity and falsifiability. Because of the prominence it

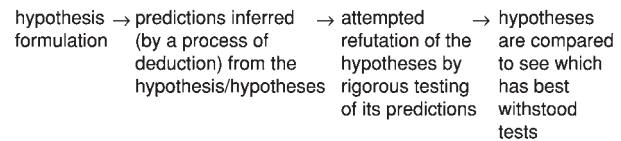

Figure 2 Popperian (falsificationist) model of science.

gives to hypothesis formation and to deductive inferences, Popper's vision of science is also known as the 'hypothetico-deductive' model.

Naturally, there are a number of alternative visions. Imre Lakatos (1970) developed a more sophisticated falsificationist model based on considering the nature of scientific research programs rather than isolated hypotheses, or sets of hypotheses. Thomas Kuhn (1970) suggested a sociological model, in which he described science in terms of paradigms. In Kuhn's view, a scientist proceeds first by learning a current paradigm. He then solves 'puzzles' using the tools available within the paradigm. Sometimes, puzzles are not solvable within the existing paradigm. If this continues, a crisis occurs that eventually leads to a 'revolution' in which the existing paradigm is discarded and a new paradigm takes its place. One important feature of Kuhn's approach is that its sociological nature means that it does not provide a means of distinguishing between scientific and non-scientific statements other than in terms of what is accepted by the relevant group of scientists. A more radical position is taken by Paul Feyerabend (1975, 1978), who claims that the notion of a reliable scientific methodology is an illusion and that scientists have failed to demonstrate that their findings have more value than any other kinds of 'wisdom.'

Whichever philosophy of science is assumed, work in linguistics fits the model as well as any other science. Linguists do not all agree about the nature of their scientific endeavor, but the majority of linguists do see linguistics as a science; and Popper's views on what constitutes scientific activity have been influential in linguistics, just as they have been in other disciplines. (For an introduction to the philosophy of science, see Chalmers, 1999).

The Scientific Study of Language

As Yngve points out, "the origins of linguistic theory can be recognized in Plato and Aristotle, but most clearly in the early Stoics from about 300 to 150 B.C." (Yngve, 1996: 14). Modern scientific linguistics began to develop in the early 19th century in the work of scholars such as Rasmus Rask, Jacob Grimm, Franz Bopp, and Wilhelm von Humboldt. Rask (1830) referred to Linnaeus and Newton in proposing that language was a natural object that should be

studied scientifically. The main focus at this time was on the comparative method, looking at similarities among different languages and using this evidence to reconstruct the ancestors of languages. (For a fuller account of the history of linguistics, see Robins, 1990.) The notion that linguistics is a science has continued since then, while assumptions about what makes linguistics scientific have changed. Perhaps the most significant developments have been the work of Ferdinand de Saussure (1972, 1983), which is usually seen as the starting point of modern linguistics; the development of a rigorous notion of linguistics as a science by Leonard Bloomfield (1926, 1933, 1970) and his American contemporaries in the first half of the 20th century; and the overturning of Bloomfield's approach by the work of Noam Chomsky (1957, 1965). In linguistics today, there are a wide range of approaches, methodologies, and notions of what is scientific, but the Chomskyan approach remains the dominant one.

Saussure's ideas established the notion that linguistics could be 'synchronic' (concerned with a particular language at a particular point in time) as well as 'diachronic' (looking at how a language has developed over time). Saussure's work had considerable influence in the development of structuralist approaches in linguistics and beyond. One particularly significant structuralist approach was that of Bloomfield and his followers in the first half of the 20th century, who developed a much more detailed view of linguistics as a science. As Robins (1990: 208) puts it, "Bloomfield was rigorously scientific, in the light of his own, mechanist, interpretation of science, concentrating on methodology and on formal analysis." It was important for Bloomfield that linguistics should be seen as a scientific enterprise, and his view of what it meant to be scientific was an empiricist one, based on behaviorist psychology. A scientific approach was an empirical study based on objective observation of facts that would lead the scientist to discover facts about languages. It was vital to avoid subjectivity. This meant avoiding hypotheses that did not emerge from objective observation, and it also meant denying the existence of the mind or of mental phenomena. This was because the data alone, considered objectively, did not justify the assumption that mental phenomena really existed. For behaviorists, all behavior could be explained in terms of external stimuli and the reflexes that they caused. Even very complex behavior, such as linguistic behavior, could be understood in terms of complex responses to stimuli. Perhaps the main concern of linguistics was to record facts about particular languages. This was given urgency by the fact that many native American languages were threatened with extinction. It was

important that they should be recorded before they were lost forever. Linguists developed a number of 'discovery procedures' that could be used to scientifically (i.e., objectively) work out facts about the languages being studied.

Chomsky's approach explicitly rejected at least the following assumptions of the Bloomfieldian approach:

- That observation should precede hypotheses
- That the ultimate aim of linguistics was to describe
- That languages were to be understood as collections of utterances (phenomena external to the mind)
- That linguistics should not presuppose the existence of mental phenomena.

Chomsky argued instead that:

- The main aim of linguistics was to construct theories of language and languages
- The ultimate aim of linguistics was to explain language and languages
- That language should be understood as a mental phenomenon (and languages as mental phenomena)
- That there was strong evidence for the existence of the human mind and a cognitive system of knowledge of language.

In general, the key notion in Chomsky's work was that there was convincing evidence for the existence of mental structures underlying human language. This evidence came from the linguistic intuitions of speakers. These included intuitions about what is and is not possible in languages they know. A famous example is the contrast between *eager to please* and *easy to please* illustrated in (6)–(7):

- (6a) John is easy to please
- (6b) It is easy to please John
- (7a) John is eager to please
- (7b) *It is eager to please John

(The asterisk is used here to indicate that most speakers judge (7b) to be unacceptable. It is also used sometimes to indicate the theoretical claim that (7b) is not grammatical in English).

Speakers of English agree that (6a) and (6b) are both acceptable and have similar meanings. Although there is no logical reason for ruling out (7b) and it is easy to see what it would mean by analogy to (6a), speakers agree that (7b) is not an acceptable utterance. This can be explained by the assumption that a cognitive system of knowledge, a grammar, licenses (6a), (6b), and (7a) but rules out (7b).

Using examples like this, Chomsky argued for the existence of mental grammars ('competence') that

underlay actual human linguistic behavior ('performance'). In Chomsky's (1986: 15–51) terms, linguistics should move from the study of 'E-language,' or 'externalized language,' to the study of 'I-language,' or 'internalized language.' This approach revolutionized linguistics, was a major influence on the so-called 'cognitive revolution' that reestablished the mind as a focus of study in psychology, and led to the establishment of the discipline of cognitive science. So what is the scientific methodology of Chomskyan linguistics like? To a large extent, it follows the Popperian model represented in **Figure 2**.

The focus of linguistics is very much on coming up with clearly stated, testable hypotheses, testing them, and constantly updating hypotheses based on how they respond to testing.

However, things are not as straightforward as this. It is not always the case that we have a theory that copes with all of the data until we come across problematic data and we then replace that theory with a new theory. Instead, we compare theories and stick with the theory that we think is the 'best so far' in that it copes best with the relevant data. Most theories do not deal with all of the existing data, and we are usually aware of problems with some data. When this happens, linguists do not reject the theory that cannot cope with the difficult data. Rather, they note the difficulty and continue with their research program until they either find a way to deal with it within the existing theory or until a new theory is formulated that deals with this data and is preferable to the existing theory when looked at overall.

In some cases, data is difficult to interpret. It may be, for example, that speakers are divided over whether a particular form is acceptable. This may correlate with nonlinguistic facts about the group of subjects, such as age (e.g., speakers over a certain age make one judgment while younger speakers make another), class, gender, or geographical location. If so, then the variation in the data can be explained based on these correlations, e.g., as a dialect difference or as a difference in the language of different age groups (which could be an example of a language change in progress). In some cases, though, there may be no obvious correlation with nonlinguistic features of the subjects, i.e., the numbers of speakers who make the different assumptions about the status of a particular form might be comparable in all groups, whether divided by age, class, gender, or geography. When this happens, linguists may 'let the grammar decide'; in other words, they may decide that whatever their existing grammatical theory predicts about the form in question is correct.

In evaluating theories, Chomsky (1986, 2000) has proposed that we can consider three 'levels of

adequacy' that our theories should aim to meet: observational, descriptive, and explanatory adequacy. A theory is observationally adequate if it describes correctly which forms are grammatical. It is descriptively adequate if it also characterizes knowledge that speakers have about those forms. It is explanatorily adequate if it provides an explanation for why the intuitions of speakers are as they are.

It is important to note that, in the Chomskyan view, a linguist's grammar is a theory about the competence of one or more speakers. So to say that a particular expression is 'grammatical' is to make a theoretical claim about the unconscious system of knowledge that speakers have about their language. This is one reason why linguists need to be careful when asking speakers for their judgments on particular utterances. Asking whether a particular form is grammatical may lead to confusion or may generate responses that reflect nonlinguistic (or metalinguistic) assumptions about the relative social status of different forms. So it is often better to ask questions like "Does this sound like a likely utterance to you?" or "Could you imagine someone saying this?"

All sciences involve idealisations. A physicist studying the effects of gravity, for example, wants to observe what a feather and a ball would do if dropped in identical atmospheres and if they were not shaped in such a way that the feather is affected to a greater extent by air resistance than the ball. Similarly, Chomsky points out that the object of study for linguistics is an idealized linguistic system:

Linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech-community, who knows its language perfectly and is unaffected by such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors (random or characteristic) in applying his knowledge of the language in actual performance. (Chomsky, 1965: 3)

This quote has sometimes been misunderstood. Chomsky is not claiming that such a speaker-listener exists. Instead he is saying that linguistics is not concerned with those nonlinguistic properties that lead to different individuals performing differently when making judgments about their language or using it (i.e., with 'performance'). So linguists are studying an object that does not exist as a physical entity. No two speakers share exactly the same language, since all speakers have acquired their language in slightly different circumstances. However, the scientific study of language requires that we abstract away from the differences to find out about the underlying language faculty. This raises a number of methodological issues. Chomsky (1980: 189–192)

makes an analogy between investigation of human language and investigation of thermonuclear reactions taking place inside the sun. It is not possible to set up a laboratory inside the sun and look directly at what is there. Similarly, we cannot view linguistic competence directly. However, we can observe light and heat emanating from the sun and make inferences based on this evidence about what is happening inside the center of the sun. Similarly, we can look at the performance of speakers of a language, including their 'metalinguistic performance' (Birdsong, 1989; Schütze, 1996), when asked to make judgments and make inferences about the system of competence that is involved in determining that performance.

In the Popperian spirit, linguistics should make no assumptions in advance about which data will be relevant in studying language, nor about what methods should be used in studying it. What is important is that hypotheses are clearly stated, testable, and tested. In practice, though, there has also always been a tendency for particular linguists to continue to use the same kinds of methods and data, so that certain groups are referred to in those terms, e.g., as 'corpus linguists' or 'intuitionists.' Much of the work of Chomsky and his followers has been based on evidence from the intuitions of speakers, gathered by personal introspection (i.e., the researcher's own intuitions) interview or questionnaire. But there is no reason in advance to rule out the relevance of other data, whether from corpora, psycholinguistic experiments, or other sources. There are constant debates about the reliability of particular kinds of data and methods for acquiring and interpreting it. Corpus data has been judged problematic because the precise data depends on the accident of who says or writes what at a particular time. Unusual but relevant data is unlikely to appear. The use of intuitions has been questioned because of the risk of subjectivity and the dependence on researchers gathering and interpreting them with enough care. And so on. But the vital thing is that the relevance of particular data is explicitly discussed and justified. As with all sciences, linguists will choose to pay particular attention to some data and to ignore other data based on the hypotheses they have adopted about what will be relevant. But the important question should always be whether the data can be shown to shed light on the particular hypothesis being investigated.

Not all linguists are theoretical linguists. Descriptive linguists aim only to describe languages, not to explain them. A descriptive grammar will aim to make clear what forms exist in a particular language. Any descriptive grammar will have to make idealisations since, as mentioned above, it is not clear that any two speakers will ever have internalized exactly the same system. Where a large percentage

of a language group agree on a particular form, it is fairly easy for the descriptive linguist to write a grammar in agreement with the majority view. In other cases, it may be much harder to decide which option to adopt. The Bloomfieldian American Structuralists who preceded Chomsky were mainly concerned with describing languages. They developed efficient methods for determining facts about languages and provided a wealth of data that theoretical linguists can use in testing their hypotheses. Descriptive linguistics continues to provide useful data with a range of practical as well as theoretical applications.

Not all linguists use falsificationist, or 'hypothetico-deductive,' methods. Conversation analysts, for example, avoid idealisations and use inductive methods to arrive at their conclusions. Conversation analysis has its foundations in ethnomethodology, a branch of sociology that grew out of dissatisfaction with the methods of sociology in the 1960s and 1970s. Research in conversation analysis is qualitative rather than quantitative and avoids early hypothesis formation. One rationale for this is that conversation is complex behavior, and explanations of it will presuppose an understanding of that complexity that cannot be justified until we find out more about the detail of what goes on in conversations. Harvey Sacks (1995), one of the originators of conversation analysis, explicitly states that he views his work as behaviorist and that this approach has much in common with the behaviorist methodology adopted by Bloomfield and the American Structuralists in the early 20th century.

One motivation for using inductivist methods is when research is qualitative rather than quantitative. Lazaraton (2002: 33) suggests that the following features can be seen to distinguish qualitative and quantitative research:

Qualitative Research	Quantitative Research
naturalistic	controlled
observational	experimental
subjective	objective
descriptive	inferential
process-oriented	outcome-oriented
valid	reliable
holistic	particularistic
ungeneralizable	generalizable aggregate analysis
single case analysis	(Lazaraton, 2002: 33)

Qualitative research is appropriate when the aim is to discover the attitudes and experiences of speakers and the motivations and processes behind events, rather than simply counting the number of times a particular event occurs. This is not to suggest that there is a necessary link between particular types of research (e.g., quantitative or qualitative) and

particular models of science (e.g., inductivist or falsificationist); neither quantitative nor qualitative research are necessarily incompatible with any particular model of science.

Not everyone agrees that linguistics is an empirical science. Some reasons for this view stem from the use of intuitions as data. Itkonen (1974), for example, suggested that the reliance on intuitions means that the claims of linguists cannot be falsified. He suggests that the occurrence of an utterance such as **girl the came in* does not falsify the claim that definite articles in English precede nouns in a noun phrase, since this utterance is 'incorrect' and the claim is about 'correct' utterances and sentences. Given this, he suggests that linguistics is different from natural sciences, in which, for example, the discovery of a piece of metal that does not expand when heated would be enough to falsify the claim that all metals expand when heated. Yngve (1996) suggests that the 'ancient semiotic-grammatical foundations' of linguistics are not compatible with modern science. As a result, he suggests putting these foundations aside and replacing them with "new foundations that are fully consonant with modern science as practiced in the more highly developed sciences of physics, chemistry and biology" (Yngve, 1996: 309). Yngve's proposal can be seen as an attempt to reconceptualize linguistics as a 'hard' science. This raises the questions of whether all of the phenomena that have been studied by linguists can fit into this new model and whether the discipline retains its interest if they do not.

For most linguists, however, linguistics is by definition scientific. While much work in linguistics can be understood in some form of Popperian, or post-Popperian, terms, there is nevertheless a wide range of views on the exact nature of the scientific study involved.

Linguistics: Approaches

Introduction

Linguistics is the study of language, and there are many different kinds of linguistics, some mutually compatible, some in competition. This diversity of approaches to linguistics is possible because language does not present itself to investigation as a coherent and well-defined field of enquiry that is clearly distinct from other areas of investigation. Instead, language is best imagined as a landscape through which it is possible to take various journeys, its horizons redefined by each approach.

Most approaches to linguistics agree on a few basic facts about language. The first is the fact of linguistic form. While the status of linguistic form is in dispute (as I show below), it is clear that linguistic events such as utterances or inscriptions must be understood as manifestations of linguistic types. Thus utterances must be understood as tokens of combinations of words, even though it may be impossible to isolate a 'word' in the actual stream of sound. The words belonging to classes (such as 'Noun') are made by selecting sounds from an inventory of sounds (phonemes of the language) and so on; in all cases, language must be understood as drawing on inventories of types and combining those types in regular ways: a word of the type 'Article' precedes a word of the type 'Noun' in English (within the Noun Phrase). These regularities, another idealization away from the crude data, involve rules or generalizations or constraints.

No account of language can ignore the fact that language is ordered and regular, based on an inventory of types and rules of combination that together constitute linguistic form. The second fact accepted by all approaches to linguistics is that form relates to meaning. A central function of language is to enable communication, and the organization of linguistic forms has some relation to the organization of meaning. This view – in some form – is shared by many approaches to linguistics: meaning is structured, and the structure of form has some relation to the structure of meaning.

The Status of Linguistic Form

One of the issues that divide approaches to linguistics relates to the 'autonomy' of linguistic form, in a number of senses. One view, expressed from the margins of

linguistics or from outside linguistic theory, is that linguists' discoveries of linguistic form are actually determined by their experience of writing (e.g., the notion of the phoneme is a reimagining of the alphabetic letter), and hence that linguistic form is an artifact of a particular moment in the history of work on language. A second view is that form is entirely determined by function; in its crudest form this is the traditional grammar notion that a word is of the class Noun if it is 'a naming word'; more sophisticated accounts might see the class of a word as fully determined by the function of the word relative to other words in the sentence. A third view sees form as autonomous; thus it is a fact about a word that it is a Noun, this having the same determinate relation to the word as its sound structure or core meaning. While it may have other characteristics as a consequence of being in this word class, including function relative to other words or distinctive phonological characteristics (e.g., stress patterns in English), these functions do not determine its status and are in effect implied by its word class rather than presupposed by it.

Of these three views, the first is an antilinguistic approach to linguistics, the second a strongly functionalist approach, and the third, a strongly formalist approach. Within the formalist approach, one of the issues that arise is which forms are primitives and which are compound or derived forms; for example, some approaches treat Noun as a primitive class, while others see it as derived from features, so that a Noun is a composite of two primitive features, +N and -V (while Verb would be -N +V, Adjective would be -N -V, etc.). The most important early discussion of whether forms are primitives is Halle's argument that there is no coherent notion of the phoneme as a primitive of sound structure; it is instead a composite entity built from the phonological features.

Underlying the discussion of the autonomy of linguistic form is the question of whether any kinds of linguistic forms are specific to language or are also found in other domains. A key text is Chomsky's *Syntactic structures* (1957). He begins his book by discussing generic kinds of forms, as expressed by rules that rewrite a symbol as a string of symbols (phrase-structure rules); simple rules of this kind could, in principle, be found in domains (including cognitive domains) outside language. But he shows that this simple kind of rule is inadequate for understanding language and that a new kind of rule – a transformational rule – must also be used. A transformational rule takes a complex linguistic representation (a tree structure) and changes it into another tree structure, and is specific to language;

transformational rules crucially do not operate on unstructured strings of symbols (e.g., no rule simply inverts the sequence of a string of symbols) but instead operate on more complex structural representations. Later developments in transformational grammar showed that transformations were subject to various constraints (such as the Complex Noun-Phrase Constraint, which prevented a rule simultaneously accessing something inside and outside a complex Noun Phrase); these constraints again were specific to linguistic form. While it has occasionally been argued that transformational rules are found outside language (e.g., in music), it is likely that this kind of rule, which transforms one complex representation into another, is specific to language. These questions are particularly interesting because the existence of some kinds of forms specific to language would support that language is processed in the mind by modes of cognitive organization specific to language.

A basic idea in linguistics is that linguistic form exists to provide formal choices that have functional (semantic or communicative) consequences. For Saussure, a sign such as the word ‘tree’ is a pairing of choices from two distinct systems: (1) the sound system, where the choices produce the three-sound sequence that make up the spoken word and (2) the meaning system, where the meaning of ‘tree’ is chosen from a range of possible meanings. The pairing of sound and meaning is thus a matter of choosing from different inventories. Choice is a dominating principle in Saussurean linguistics and, later, in structuralism, including the nonlinguistic structuralism found in the work of Roland Barthes such as *The fashion system*.

Systemic functional grammar is one of the major approaches to linguistics in which the notion of choice has been fundamental. Each ‘system’ in systemic functional grammar presents ranges of options to choose from when communicating, and the theory investigates the functions expressed by making these choices. This approach has enabled systemic functional grammar to pioneer work in certain areas of linguistic description, some of which (such as Halliday’s early work on thematic roles) have been absorbed into other linguistic theories. In particular, systemicists are interested in the choices among ‘cohesive devices’ in discourse, the devices – conceived of as choices from a range of options presented by the system – explicitly guiding the hearer or reader in understanding how sentences are related.

Systemicists have developed an account of ‘register,’ the set of linguistic features associated with specific genres of verbal behavior (formal interview, informal letter, etc.), where the term ‘register’ itself

is another way of saying ‘range of options from which to choose.’ In addition, systemic functional grammar has a deep interest in stylistic analysis, in which formal choices have functional significance in expressing complexities and nuances of meaning and fit well with ‘close-reading’ approaches in mainstream literary criticism.

Another fundamental idea, shared to some extent by all approaches, is that linguistic form is the mediation between a thought and an utterance; that is, that linguistic form enables the expression of meaning in sound (and writing). Chomsky’s ‘minimalist enquiries’ begin by re-examining this basic idea. From his earliest work onward, Chomsky’s approach to linguistics has always been to ask what the simplest kind of language might be, and then to ask why actual human languages are not this simple.

Thus, as described above, *Syntactic structures* establishes that sentences of a natural language cannot be generated just by rules (phrase-structure rules) of a certain low level of complexity, but require a more complex kind of rule, one that in turn requires a whole theory of linguistic representations which can be subject to transformation.

‘Why aren’t sound and meaning fully aligned?’ is a recently formulated minimalist question; the answer is that organizations of the sentence as meaning are not isomorphic with large-scale organizations of the sentence as sound. In Chomsky’s always-provocative terminology, the question is why language is ‘imperfect.’ Consider, for example, the Noun Phrase that expresses the thing eaten in ‘John ate the cheese’; here this unit of meaning is after the verb, but it is before the verb in ‘the cheese was eaten’ and the word ‘what’ (which substitutes for it, i.e., ‘the cheese’) is at the beginning of the sentence in ‘what did John eat?’ Perhaps the unit of meaning does not always stay in the same place because some other principle, possibly involving the informational structuring of the utterance, forces it to move. Chomsky sees this as an ‘imperfection,’ and seeks to explain why moving the unit is a necessary compromise among the various demands placed on linguistic form by the requirement that speech expresses meaning.

Rationalist and Empiricist Approaches and the Status of Data

A major division in approaches to linguistics pits rationalists against empiricists, as their attitudes towards data exemplify. The key figure for rationalist approaches is Noam Chomsky. Most kinds of linguistics before Chomsky were empiricist approaches (as in the work of Bloomfield), and Chomsky defined his linguistics in opposition to those. Data always

present a problem for linguistics, because it must always be idealized; two slightly different utterances of the same word must be understood by linguistic theory as two tokens of the same type. Without this idealization, there would be nothing to say about language.

Approaches differ in the kinds of idealizations they adopt. Chomsky famously and substantially idealized so that the rules in *Syntactic structures* generate an (infinite) set of sentences corresponding to the set of sentences accepted as grammatical by an idealized user of the language, having separated out all contextual and behavioral factors. The rules describe what someone knows to be grammatical (his or her ‘competence’), not what that person actually says.

Since this rationalist approach to linguistics aims to describe a person’s knowledge of language, not his or her linguistic behavior, there are some significant consequences for the status of data. First, data must be sifted into the relevant and the irrelevant (for this particular purpose); data irrelevant for theoretical syntax might of course be relevant in a different kind of linguistics. It is never clear in advance whether data will be relevant or irrelevant. For example, in *Syntactic structures* Chomsky demonstrates that transformational rules can explain the various configurations of modal, auxiliary, and main verbs in an English sentence; on the other hand, it’s also possible, since a finite and small number of such possible configurations exist, that they could actually just be learned as fixed sequences with no rule involved. There is no guarantee in advance that either approach will be correct.

The second major consequence of a rationalist approach to data is that the frequency of any particular kind of data is ignored, both in the sense that in Chomskyan linguistics ‘variability of rules’ is generally ignored (see discussion below) and in the sense that statistically very rare data may nevertheless have a key theoretical role. Thus, in the early 1980s the rare ‘parasitic gap constructions’ were first discussed; an example is the grammatical sentence ‘Which books did you put on the shelves without reading?’ where the phrase ‘which books’ matches not one but two gaps in the sentence (after ‘put’ and after ‘reading’), one of which is called parasitic. Sentences like this are unlikely to turn up in a corpus, and there are no descriptions of them before this time; nevertheless, such sentences played a major role in helping us understand fundamental aspects of the workings of sentence structure.

The third major consequence for data under a rationalist approach is that these data are invented in order to test the predictions of the theory

(i.e., invented and then tested against speakers’ judgments), rather than gathered and used in constructing a theory. Rationalist approaches to linguistics must assume that the theory will guide the interpretation of the data.

In contrast, empiricist approaches treat theories as constructs that emerge from data. These data may be gathered into a corpus. A fundamental concern is to develop a methodology for gathering, annotating, and understanding the data. Note that rationalist approaches to linguistics do not have this commitment to a methodology, and one of Chomsky’s aims in *Syntactic structures* was to wrest American linguistics from the heavily method-oriented approach associated with the structural linguistics of the 1930s and 1940s.

One advantage of the empiricist approach is its inherent ability, more so than a rationalist approach, to guarantee a result in the sense of a description or annotation of linguistic data. An empiricist approach can be conceptualized as a plan of action, with steps to be followed using clearly specified methods in order to process a collection of data into an account. Because an empiricist approach is supported by agreed methodologies, it can be used to gather and organize large amounts of data, and it is sometimes favored in language work when large amounts of information must be gathered before that information (e.g., from ‘endangered languages’) becomes unavailable.

This kind of empiricist approach also favors the social over the cognitive, because what is gathered is what people say or write, rather than what they know. It has been argued (for example, by Ken Hale) that a rationalist approach, despite its associated risks, is nevertheless best even for endangered languages, because we should be interested in these speakers’ knowledge of their language, not just in their utterances.

While approaches to linguistics agree on the existence of linguistic form, they disagree on how inclusive such a theory of linguistic form should be. One area of disagreement is language statistics. As with any collection of data, linguistic data can be subjected to statistical analysis and this statistical analysis can be described in terms of linguistic rules.

It is a fact that some linguistic rules are ‘variable’ for an individual speaker or for a speech community (the term ‘variable rule’ comes from Labov); an example would be ‘t-glottaling’ in British English or the ‘r-drop’ in some varieties of American English. T-glottaling is the use of a phonetic glottal stop where there is a phonemic /t/ in a word like *bottle* and that can be understood as a consequence of applying a rule changing /t/ to the glottal. Data gathered for a

particular individual will show that the rule is used at some times and not at others, and that these data could be described by attaching a percentage to that rule for that individual (for that data) to indicate how frequently the rule is actually applied in a particular context. The percentage might differ with the social context; for most speakers, t-glottaling is more likely in more informal contexts, and this information could be appended as a statistic to the rule.

The issue dividing approaches to linguistics is whether a way of relating that percentage to the rule can be built into the theory and the representations it permits. The decision depends in part on whether the theory aspires to the holistic or the modular. Holistic theories attempt to incorporate as much explanation of language as possible within a single, connected theoretical model, e.g., Systemic Functional Grammar. Such theories tend to be functionalist and tend not to allow for significant autonomy of form; the holism here claims an explanatory link among various different aspects of language.

Modular theories, on the other hand, are theories that divide language into different subfields – each with its own theoretical account – where there may be limited or no relation among the theories. Modular theories, of which generative grammars are a good example, place considerable emphasis on the autonomy of linguistic form. While generative linguistics on the whole is not interested in statistical facts, Optimality Theory (which has emerged from generative linguistics) is interested; it has had a consistent interest in statistical facts, and various ways have been suggested of incorporating statistical facts into the ranking of constraints.

The distinction between rationalist and empiricist approaches is sometimes entangled in a rhetoric of ‘realism’ or ‘naturalism.’ The terms ‘natural’ or ‘real/realistic’ may be used to valorize certain kinds of (usually empiricist) linguistic theory; hence there is talk of ‘natural phonology,’ ‘psychological realism,’ or ‘real language.’ The underlying assumption in each case is that how linguistics proceeds should be subject to some external constraint on theory-formation, but that is in conflict with the basic principle of rationalist approaches that no theory is guaranteed by some external constraint to be right or successful.

Most commonly, external constraints are drawn from computer science or from psychology, but sometimes a demand is heard that linguistic theory should be constrained by a particular audience’s need to understand it. In each case, these demands are driven by practical anxieties, usually fundamentally financial: Can the theory be used to develop working software? Can it serve psychology? Will the general public understand it sufficiently to want to support it? Will

the linguistics department survive the next round of university cost-cutting?

The Production of Form

All approaches to linguistics agree there is linguistic form. As I have suggested above, these approaches differ on which forms are considered fundamental; for example, are phonemes a fundamental kind of form, or are they a construct based on phonetic features that themselves are the fundamental kinds of forms? They also differ in how linguistic form is generated. What kinds of rules build form? What are the constraints on the operation or output of those rules? Much of the debate in this area has been conducted within kinds of linguistics that refer to themselves as ‘generative’ and trace their intellectual ancestry back to *Syntactic structures*, a book that is a key discussion of the role of rules in language.

In early generative linguistics, there were just rules. These were phrase-structure rules that built a representation called a tree structure, which terminated in a string of words that made up a grammatical sentence, and there were transformational rules that changed one tree structure into another. Within a few years, it was noted that transformational rules were subject to constraints, and these were explored fully by J. R. Ross, who in 1967 wrote one of the most influential Ph.D. dissertations in linguistics, ‘Constraints on Variables in Syntax’ (published as *Infinite Syntax!*, 1986). Ross (1967) showed that the possibility of changing one tree structure into another was prevented if the transformational rule needed to relate two positions, one of which was in an ‘island’ (a relationally defined subarea within a tree structure, such as a sentence inside a noun phrase). This meant that in addition to rules that generated form, there were also constraints on the rules.

The balance between rules and constraints – both in terms of number of rules as opposed to constraints, and complexity of rules as opposed to complexity of constraints – has changed over the course of generative linguistics and is different in different approaches. For example, by the early 1980s, transformational rules were as simple as the rule ‘move something’ (technically formulated as ‘move alpha’), while the constraints on this simple rule were quite extensive and complex.

In addition to constraints on rules, another kind of constraint was introduced: a constraint (or ‘filter’) on the output of the rules. The best known filter in generative syntax of the 1970s was the ‘that-trace’ filter; this stated that a transformational or other rule could not have as its output a sentence in which the subordinating conjunction **that** was followed by

a 'trace' (an empty subject). Thus the sentence 'Who did you say that left?' is ungrammatical because **that** is followed by an empty subject.

Given the possibility of having rules, constraints on rules, and constraints on outputs, some theories have attempted to dispense with one of these elements. In the syntactic theory of the early 1980s called 'government-binding theory,' the terms government and binding did not describe rules but were best understood as expressing constraints on relationships among parts of the tree structure; the role of rules was minimized. In Optimality Theory, both in syntax and in phonology, the role of form-generating rules is minimized, and there are no form-changing rules (such as transformational rules); instead, the burden of explanation is carried by constraints on output.

Optimality Theory, which has been dominant in approaches to sound structure, participates in a key debate about order. In Optimality Theory, constraints are ordered (the term 'ranked' is used) in the sense that an output may violate a constraint and yet be preferred to an output that violates another constraint, because one constraint is ordered above the other. However, this order is fundamentally different from that of the generative phonology that dominated phonology before Optimality Theory, and Optimality Theory now challenges it. In this generative phonology, rules are themselves ordered, such that the input of one rule is determined by the output of the preceding rule. Rule ordering is also the basis of the phonological cycle, where a sequence of rules is applied to a word, then morphological rules are applied (e.g., it is suffixed), and then the same sequence of phonological rules is applied again from the beginning.

The 'Landscape' of Language and its Division into Fields of Linguistic Inquiry

As we have seen, approaches to linguistics can disagree on what aspects of language are open to theoretical description. Alternatively, these approaches may agree on what should be described but dispute the subfield most suited to describing it. Linguistic theory is conventionally divided into distinct but related subfields. For sound structure there is a distinction between phonetics (itself potentially distinguished into acoustic and articulatory phonetics) and phonology; phonetics deals with the mediated manifestations of sound, while phonology deals with the knowledge of (representations of) sound. Here a 'border dispute' involves the distinctness of phonetics and phonology and whether the same kinds of description – e.g., the same kinds of articulatory feature – can be used explanatorily in both phonetics and phonology.

The distinct status of morphology is another area for dispute. In some theoretical frameworks, morphology and phonology are closely intertwined (e.g., lexical phonology and morphology), and thus questions arise about the similarity between morphological and phonological processes. Some morphological processes, such as reduplication (where part of a word is copied to build a larger word), raise difficult problems for phonology. However, morphology is also syntactically relevant, and it is possible that the internal structure of words – the domain of traditional morphology – can in some cases be opened up to syntactic rules. Reorganizing subkinds of linguistics relative to one another can create very productive ways for approaches to linguistics to develop and change.

Another border under dispute is that between the syntax and the pragmatics. This can involve matters of information structure, as well as problematic areas of the syntax such as apposition and conjunction, where there may be pragmatic explanations for apparently syntactic processes. Does the organization of discourse require its own subfield ('discourse analysis') or can it be entirely incorporated under the field of pragmatics? Could a theory of discourse analysis better explain coreference than the syntax?

In his recent work, Chomsky argues that some phenomena previously understood as syntactic are better understood as phonetic – explained as part of the 'phonetic form' of the sentence rather than its syntactic form. Here, for example, an interesting issue is whether the linear order of syntactic elements (such as words) can be entirely explained by some nonsyntactic principle such as the phonetics, on the basis that syntax is the study of hierarchy and phonetics the study of sequence.

Approaches to linguistics can thus differ according to the linguistic material that experts think they can explain under their own subfield. But it is also possible for approaches to different kinds of data to share similar ways of theorizing, a fact that has interesting implications for the organizations of different kinds of linguistic cognition corresponding with these theories. The most significant interplay among domains is seen in generative phonology and generative syntax. At times these have been very close – and at other times very different – in their approaches, raising the question as to whether there are good reasons for thinking that phonology and syntax are fundamentally alike or fundamentally different.

A historical connection, now broken, was in the idea of the 'cycle,' where a linguistic object (such as a word including several suffixes or a sentence including several subordinate clauses) was built in stages; at each stage, the full set of rules was run through

in sequence, starting again from the beginning at the next stage. For a period, it seemed that both words and sentences could be understood as constructed ‘cyclically’ in this way. While the basic notions of this cycle still survive in some forms and in some types of linguistics, few would now argue for the cycle as a point of similarity between the two theories.

Another rich collection of interconnections involves the notion of the ‘feature,’ an idea that also jumped from linguistics to Claude Lévi-Strauss’s anthropology in the 1940s. Form understood as a set of features – each valued as + or – (such that two features can build four derived forms) – has not only been central to generative phonology, but also borrowed as an idea for (1) syntactic categories (e.g., the category of noun is a derived form based on the features +N –V), (2) semantic categories (e.g., ‘agent’), and (3) in lexical semantics (where meanings are considered composites of underlying ‘meaning features’).

More recently, the principles of Optimality Theory, which have been widely used in phonology, have been borrowed to explain syntactic phenomena. Thus, one characteristic of approaches to linguistics is a willingness to borrow ideas from other domains. When the same idea works in different linguistic domains, this

promises to tell us something fundamental about the organization of linguistic form.

Introduction

Language makes us human.

Whatever we do, language is central to our lives, and the use of language underpins the study of every other discipline. Understanding language gives us insight into ourselves and a tool for the investigation of the rest of the universe. Martians and dolphins, bonobos and bees, may be just as intelligent, cute, adept at social organization, and morally worthwhile, but they don’t share our language, they don’t speak ‘human’. Linguistics, the scientific study of language, seeks to describe and explain this human faculty. It is concerned with three things: discovering precisely what it means to ‘know a language’; providing techniques for describing this knowledge; and explaining why our knowledge takes the form it does.

These concerns may seem too obvious to need discussing, but the complexity of our knowledge of language becomes strikingly apparent when we see someone lose their language after they have had a stroke, or when we observe an infant who has yet to acquire the faculty that we deploy so easily. To understand these three concerns, we need a theory, and that is what linguistics provides.

The Meaning of ‘Language’

That linguistics is ‘the scientific study of language’ has become a cliché, but what it means to be ‘scientific’ may not always be obvious, and what people mean when they use the word ‘language’ varies from occasion to occasion. Consideration of what is involved in being scientific is deferred until later in the essay, for now it suffices to observe that only a few aspects of language have been illuminated by theoretical (scientific) linguistics, so there are many areas where it has little, if anything, helpful to say.

The situation is akin to that in biology, viewed as the science of living things. Despite their importance to us, biology has nothing to say about the definition of pets; similarly, despite their relevance to us, linguistics has nothing to say about the definition of dialects.

In everyday usage, 'language' is used differently, depending on whether it is construed as a property of the individual, of society, of the species, or as an autonomous entity in the world. Linguists working in the tradition of 'generative' grammar, the framework that has dominated linguistics for the last 50 years, argue that an 'individual' approach to language is logically prior to any other, but in principle we have the possible domains shown in (1), each suggesting different kinds of questions:

- (1) Language and the Individual
 - Language and the Brain
 - Language and Society
 - Language and the Species
 - Language and Literature
 - Language and the World

Looking at 'Language and the Individual', the central question raised is 'what constitutes our "knowledge of language"?' What properties or attributes does one have to have to be correctly described as a speaker of English, or Burmese, or any other 'natural language' – the term linguists use to refer to languages naturally acquired and spoken by humans, as opposed to the 'artificial' languages of logic or computing? An extension of this question is how and where knowledge of language is represented in the brain, and what mechanisms need to be postulated to enable us to account for our use of this knowledge. Neurolinguistics is an area of remarkable growth, supported by technological advances in imaging.

Under 'Language and Society', sociolinguists raise questions such as 'What are the social variants (class, age, gender, power) that determine, or correlate with, the use of particular forms of the language?' A woman might use some pronunciations or grammatical constructions with statistically significantly greater frequency than a man of the same age, or a female of a different generation. For the world's multilingual majority, social considerations may even determine which language is used in specific situations. A Swiss from Graubünden might use Romansh at home, Swiss German at work, and High German at a conference.

Looking at 'Language and the Species', we might be preoccupied with the puzzle that all human children learn their first language with seeming effortless-ness, while the young of other species, however intelligent, show minimal such ability. Linguists, and researchers in related fields, investigate not only

whether this claim to uniqueness is indeed true but, if it is, how the faculty evolved.

When we turn to the relation between Language and Literature, we confront several issues: 'What is literary form?'; that is, what are the linguistic properties that make something a novel or a novella, a sonnet or an epic? How are literary effects achieved? What are the linguistic characteristics of a particular style?

Looking at 'Language and the World' raises issues of three different kinds. First, how does language relates to things outside the head? That the word 'London' refers to the capital of the United Kingdom is innocuous enough as an informal claim, but it raises interesting, and vexed, philosophical questions. The debate revolves around the status of language as a property of an individual, rather than as an entity with independent existence. This 'external' notion of language is presupposed by those who write irate letters to the press, inveighing against split infinitives, and lamenting the fact that our language is becoming degenerate, either because of the sloppiness of modern youth, the pernicious influence of text messaging, or the role of multiculturalism. The third issue is in many ways the most obvious and the most puzzling: Why are there so many languages? Why does 'human' have so many dialects?

Knowledge of Language

The generativist claim that study of the individual's knowledge of language must be the first or exclusive focus of a scientific linguistics is controversial; that it is a possible, indeed necessary, focus is not seriously in doubt. This individualistic claim implies that linguistics is a branch of psychology, ultimately biology, rather than, say, of sociology. This is not to deny that there are interesting domains of knowledge that take the social conditions of language use as their central focus; it is rather to claim that there is a psychological enterprise which looks at one branch of human cognition and which lends itself to rigorous investigation and, moreover, that it is logically prior to looking at the exploitation of this knowledge in society. This focus on knowledge is highlighted in the claim that the subject of linguistics is 'I-language', rather than 'E-language', where the 'I' stand for *internal* to a particular individual, and 'E' stands for *external* (to the mind of the individual). A corollary of this orientation is that the descriptions that linguists devise are said to be 'psychologically real', where this is not a claim about psychological experimentation or the kind of evidence used in formulating particular linguistic hypotheses, but is simply the claim that we are investigating the human mind and that

current theory is the closest approximation to the truth that we have.

The mind is ultimately a product of the brain (and other systems), and evidence about the mental can sometimes be gleaned from studies of the neural. In general, however, linguists remain agnostic about the details of the relation between the mind and the brain (frequently referring simply to the ‘mind/brain’). That is, we devise theories of a sub-part of human knowledge, but whether that knowledge is localized in the temporal lobe of the left hemisphere, or is distributed throughout the brain, or whatever, is less important. This is not because of lack of interest, but simply because – at present – theories of neural structure are too embryonic to cast much light on linguistic generalizations. Different languages allow different word orders, so that Japanese puts the verb at the end of the sentence and English puts it in the middle. Linguistic theory must provide the means for describing and ultimately explaining this fact, but at present we have no inkling of how the difference between a Japanese and an English speaker might be neurally implemented, so the neurological structure of (this bit of) the language faculty is still a closed book.

What do you have to know to count as a ‘speaker’ of a language? If you say you speak English, it implies that you understand English, too. The point may seem trivial, but knowledge of language is neutral between speaking and hearing; both activities draw on the same fund of knowledge. There is no known illness or accident which leaves you able to speak only English and understand only Portuguese, for instance. This is not to deny that you may be better at talking than listening; or that you may suffer brain damage that leaves you unable to speak while you remain perfectly able to understand. A particularly poignant example of this is provided by Bauby’s autobiographical account of ‘locked-in’ syndrome, where a stroke left the author speechless, but with his language and his ability to understand intact. In normal, non-pathological, cases, however, your ability to *utter* (2a):

(2a) Giraffes have long necks

(2b) Giraffes have necks long

involves the same ability that enables you to *understand* (2a), and also to judge that someone who mistakenly says (2b) has got it wrong. The implication of this observation is that the primary focus of linguistics is on characterizing this neutral knowledge, rather than the mechanisms of speaking, hearing, and judging that are parasitic on it. In other words, linguistics is (largely) about one form of cognition, and only secondarily about the deployment of that

cognitive ability. In the standard terminology, this is known as the ‘competence-performance’ distinction. Your knowledge of language (your competence) underlies your ability to speak, to understand, and to give judgements of well- or ill-formedness (your performance). You may be knocked unconscious and be temporarily unable to speak or understand, but your knowledge typically remains intact – you have competence with no ability for performance. The converse situation, in which you could perform in the absence of any competence, does not occur, though it may characterize the ‘linguistic’ capabilities of the average parrot, which may be able to utter entertaining sentences of what sounds like English, but presumably without the knowledge of English grammar that underlies our abilities.

To count as a speaker of English, you need first to know a large number of words: not just nouns, verbs, and adjectives – words such as *cat* and *go* and *pretty*, whose meaning is relatively transparent, but items such as *the*, *under*, and *however*, whose meaning and use are less easy to specify. Of course, not everyone has the same vocabulary: I may know technical terms in linguistics that you are ignorant of, and you may be familiar with words pertaining to reggae or arachnology that I don’t know, but if either of us were ignorant of words such as *mother* or *and*, people might be justifiably reluctant to classify us as speakers of English.

In addition to knowing the words of a language, you need to know what to do with those words – you need to know the grammar. Our knowledge of language falls into two compartments – the vocabulary (or ‘lexicon’) and the ‘computations’ we can carry out using that vocabulary. This computational system, comprising syntax and morphology, is surprisingly complex, and enables us to produce baroque examples such as Chomsky’s (1995: 88) *Who do you wonder whether John said solved the problem?* Such sentences are of marginal acceptability and citing them may strain the tolerance of outsiders, but this marginal status may itself provide crucial evidence for or against some theoretical claim concerning our knowledge. Henceforth, I shall assume that you and I have the same I-language, abstracting away from differences in vocabulary and grammar. Fortunately, it’s enough for the present purposes to look at the more basic, but nonetheless rich and surprising, knowledge we have of words as simple as *be* and *the*. Consider the examples that follow, which illustrate a wide range of things you know, even if you weren’t previously aware of knowing them. It’s self-evident that *is* and *have* mean different things, as shown in (3), but sometimes they seem to be used interchangeably as in (4):

- (3a) Tom is a problem
- (3b) Tom has a problem
- (4a) Tim is yet to win the Booker prize
- (4b) Tim has yet to win the Booker prize

How is it that something as basic as *is* can sometimes get the same interpretation as *has* and sometimes a different one? Or consider the so-called definite article (*the*), which is often said to mark the distinction between entities which are already familiar and those which are new, as in (5a) and (5b) respectively:

- (5a) My friend likes the penguins
- (5b) My friend likes penguins

But this characterization is not adequate to account for the rather macabre effects found in the newspaper report in (6b) beside the relatively unexceptionable (6a):

- (6a) The woman had lived with the dead man for two years
- (6b) The woman had lived with a dead man for two years

Still less can it account for the fact that on occasion the presence or absence of *the* seems to indicate the difference between subject and object, as in (7):

- (7a) This man is in charge of my brother
- (7b) This man is in the charge of my brother

In (7a) *this man* has control of *my brother*; in (7b) *my brother* has control of *this man*. So what does *the* really mean? Does it even make sense to ask such a question?

Take a more complex example: the word *last* is multiply ambiguous: apart from its use as a noun or a verb, it can function as an adjective meaning either 'final' or 'previous', as illustrated in (8):

- (8a) This is your last chance
- (8b) Your last example surprised me

This ambiguity can result in dialogues which have strikingly different interpretations, as in the alternatives in (9):

- (9) Q "What were you doing in Paris?"
- A1 "Oh, I was collecting material for my last book"
- A2 "Oh, I'm collecting material for my last book"

Answer 1 is itself ambiguous, with either meaning possible for *last* (though 'previous' is the more easily accessible); Answer 2 has only the interpretation that the book under discussion is planned to be the final one I write. The difference must be attributable to the contrast between the past and the present tense,

as that is the only way the sentences differ, but it's not obvious why sentences should be ambiguous or not depending on the tense they contain.

Linguists thrive on such ambiguity, as it regularly provides evidence for structural differences that may not be otherwise apparent. A simple example is provided by the inscrutable notice outside our local school, given in (10):

- (10) This school accepts girls and boys under six

Whether the school accepts girls of any age but only small boys, or no children over six is indeterminate without more information. As we shall see under the section 'Describing Knowledge of Language,' (10) has two quite different syntactic structures corresponding to the two meanings. Similarly the fact that (11) has a number of different interpretations can give us clues as to how to analyze the various possibilities:

- (11) My son has grown another foot

If my son has become taller, the example is parallel to (12a); if he is a freak or a remarkably successful gardener, there are other possibilities, as shown in (12b) and (12c), suggesting that *another foot* in (11) may be correctly analyzed either as a measure phrase or as a direct object:

- (12a) He has grown by another foot
- (12b) He has grown a third foot
- (12c) Another foot has been grown (in this flowerpot)

Such differences of interpretation make the complexity of our knowledge apparent, but unambiguous examples can be just as illuminating and can simultaneously provide evidence against the traditional philosophical claim that meaning can be adequately treated in terms of truth. Thus, we know that (13):

- (13) My first wife gave me this watch

suggests rather strongly that I have been married more than once, but I can utter it truthfully despite having been married only once: my only wife is presumably my first wife. The example is misleading, not false, and so implies that there is much more to meaning than mere truth. As shown by Chomsky's (1957) famous *Colorless green ideas sleep furiously*, structure and meaning (syntax and semantics) can dissociate, so we also know that, despite being initially plausible and syntactically unexceptionable, (14) is meaningless:

- (14) More people have visited Moscow than I have

All the preceding examples illustrate both our knowledge of vocabulary and how it interacts with

(syntactic) structure. The responsibility of linguistics is to describe the full range of such facts, not just for English, but for all human languages. Then, in virtue of its scientific pretensions, it has to (attempt to) explain why these facts rather than any others are the ones that occur – again both in English and in other languages. To do justice to the richness of what we know, it is necessary to distinguish not just the lexicon and the computational system, but to differentiate among syntax, semantics, morphology, phonology and phonetics, and to relate this knowledge to pragmatics – how we interpret utterances in context.

Take our knowledge of morphology, the internal structure of words. We know that *thick*, *thicker*, *thickest*, and *thicken* are all words of English, but that there is no *thinnen* to accompany *thin*, *thinner*, *thinnest*. We know that *thick* relates to *thicken* and that *rich* relates to *enrich*, whereas *richen* is slightly odd, and *enthick* is impossible. This knowledge can't just be a result of our never having heard *thinnen* or *enthick* before, you may never have heard *texted* before, as in "I've just *texted* an urgent message to Fred", but you know that that is possible. As linguists, we may also know that some languages, such as Vietnamese, have almost no morphology: words in this language have none of the internal structure characteristic of affix-rich items such as *indecisiveness* or *rearranged*. On the other hand, some (polysynthetic) languages, such as Inuktitut (Eskimo) or Mohawk pile one affix on top of another so that words are often strikingly complex, and correspond to whole sentences in English. Baker (2001: 87) gives the Mohawk example in (15) with the meaning "He made the thing that one puts on one's body ugly for her":

(15) Washakoty'a'tawitsherahetkvhta'se'

Our knowledge of phonology, the sound structure of language, is equally rich. We know that *past*, *spat*, and *stap* are possible words of English, indeed they all exist; that *stip* and *stup* are also possible words, even though they happen not to exist; but that *satp*, *ptas* and *tpas* are not even possible words. Apart from knowing the segmental make-up of words, we also have knowledge of 'supra-segmentals': that *photograph* is stressed on the first syllable, *photographer* on the second, and *photographic* on the third. Two points need to be made: first, we 'know' this in the sense that we produce the correct pronunciations on demand, and we recognize that deviations from these pronunciations are slips of the tongue or foreigners' mistakes; that is, knowledge of language need not be immediately available to conscious introspection. Second, the characterization in terms of 'first', 'second', and 'third' syllable is actually not the correct

theoretical characterization of our knowledge. As we shall see below, rules of grammar (including phonology) cannot count.

We know more. In an example such as (5a) above, *My friend likes the penguins*, we have to account for the pronunciation of *the* before the initial 'p' of *penguins*: a pronunciation rather different from that of the same lexical item *the* when it occurs before a vowel, as in *My friend likes the otters*. Knowledge of this kind is supplemented by phonetic knowledge which is even harder to bring to consciousness: that the 't' in *photographer* is aspirated, but the 't' in *photograph* is not; that the 'r' in *grime* is voiced, but that in *prime* it is slightly devoiced; that the vowel is longer in *wed* than in *wet*. Such facts belong to the domain of phonetics, the field that deals with the sound properties of language in general, rather than the sound structure of a particular language.

Our phonological knowledge is not self-contained, but may interact in complex ways with our knowledge of the rest of the grammar. We know that (16a) has an alternative pronunciation of the kind given in (16b), where *is* is 'contracted' to's, but that (17a) cannot be matched by the impossible (17b) (impossible is indicated by the asterisk), despite the apparent similarity of the examples:

- (16a) The prime minister is a war criminal
- (16b) The prime minister's a war criminal

- (17a) The president is a war criminal and the prime minister is too
- (17b) *The president is a war criminal and the prime minister's too

An understanding of such asymmetries requires investigation of the relation between syntactic and phonological processes, and relies on an analysis of empty categories: entities that have syntactic and semantic properties but are silent.

In addition to phonology and morphology, we need to account for the (semantic) fact that sentences have meaning. The examples in (18) exploit most of the same words but their meanings are radically different:

- (18a) My friend likes the penguins
- (18b) The penguins like my friend
- (18c) My friend doesn't like the penguins

Moreover, the semantics is 'compositional' – except for idioms, the meaning of a sentence is a function of the meaning of its parts, and their syntactic configuration. The meaning difference between (18a) and (18b) is dependent on which item is subject and which object, notions that can be defined syntactically. In fact, life is a little more complicated than that, as the semantic interpretation of 'subject' is not uniform, and we need to advert to 'thematic relations'

involving ideas of agentivity and patienthood, as shown by the minimal pair in (19):

- (19a) John undertook the surgery reluctantly
(19b) John underwent the surgery reluctantly

John is the subject in both sentences, but is the agent (the surgeon) in the former, and the patient (in both senses) in the latter. These relations are internal to a single sentence, but we also need to relate (the meanings of) different sentences. There are two possibilities: relations which depend on the meaning of individual words, and relations which are purely sentential in that they are independent of such lexical relations. An example of the former is illustrated by (20):

- (20a) Mozart persuaded da Ponte to write a libretto
(20b) Da Ponte intended to write something

where (20b) follows, by virtue of the meaning of *persuade* from (20a). An example of the latter is provided by pairs such as (21a) and (21b), where the truth of (21a) guarantees the truth of (21b):

- (21a) Torture is immoral and should be illegal
(21b) Torture is immoral

In the next section, I will outline some of the descriptive mechanisms exploited by (generative) linguistics; then I will try to show how we can approach an explanation for at least some phenomena, looking at a range of examples from English and elsewhere, and use this extension to substantiate the claim that linguistics is a science. Throughout, I shall concentrate on **syntax**. Phonology and phonetics, morphology, and semantics are rich disciplines in their own right, each with a massive literature, but the essence of the analysis of sentences is their **syntactic structure**. And life is finite.

Describing Knowledge of Language

Sentences have structure of various kinds. Returning to the example, *My friend likes the penguins*, we need to describe it in different ways at several distinct ‘levels of representation’: phonological, semantic, and syntactic. Thus, it can be pronounced in a variety of ways – with stress on *friend* or on *penguins*, for instance, with concomitant differences of interpretation. Restricting attention to the syntax, it is intuitively clear that *my* and *friend*, and *the* and *penguins* ‘go together’ in a way that *friend* and *likes*, and *likes* and *the* do not. Each initial word of *My friend* and *the penguins* enables us to pick out some individual or individuals in the world, whereas *friend likes* and *likes the* have no such function within them. This intuition is accounted for in terms of ‘constituency’

represented by means of a simplified tree diagram of the kind in (22):

The top of the tree (IP) indicates that the whole sequence “*My friend likes the penguins*” is an ‘I(nflection) P(hrase)’ (it used to be called ‘Sentence’, but the terminology has changed to reflect changes in our understanding). The IP ‘branches’ into an NP and a VP, where ‘NP’ means ‘Noun Phrase’, that is a sequence consisting of a Noun (N) and something else, and ‘VP’ stands for ‘Verb Phrase’, that is a sequence consisting of a Verb (V) and something else, here in this instance another Noun Phrase. The verb is the (present-tense) form *likes*, and the two Noun Phrases each consist of a Noun (here the singular *friend* and the plural *penguins*) preceded by a ‘Det(eterminer)’, respectively *my* and *the*. Each of ‘IP’, ‘NP’, ‘VP’, ‘N’, etc., are referred to as ‘nodes’ in the tree; IP, NP, and VP, etc., are said to ‘dominate’ everything below them, and to ‘immediately dominate’ everything immediately below them. So VP dominates all of V, NP, Det, N, *the*, and *penguins*, but immediately dominates only V and NP, which are known as ‘sisters’. Once one has got used to the jargon, the advantages of such an analysis are many: it simultaneously shows the linear sequence of items – the order they come in – and the relationships among the component parts: so *the* and *penguins* are more closely related, by virtue of being NPs, than are *likes* and *the* which do not form a ‘constituent’ of any kind. A constituent is defined as any sequence of items that can be traced exhaustively to a single node in the tree: *likes* and *the* can be traced back to VP (and indeed IP), but these nodes dominate other material, too (*penguins*, for instance) so *likes the*, like *friend likes*, are not constituents.

We now have an explicit way of characterizing the example *This school accepts girls and boys under six*. The two interpretations of the object, *girls and boys under six*, can be represented with different constituent structure as in (23):

- (23a) [girls] and [boys under six]
(23b) [girls and boys] [under six]

where the brackets mark the constituents, and indicate that the ‘scope’ of *under six* is respectively either just *boys* (23a) or includes *girls and boys* (23b).

In addition to this syntactic constituent structure, there is morphological structure to deal with: the fact that *penguins* is plural is marked by the addition of the suffix *-s* to the base *penguin*, and the opposite order (with *s-* prefixed to *penguin* to give *spenguin*) is impossible (in English). Investigating the full range of such facts in the world's languages is a matter of intensive research, and addresses the same immediate task of accounting for how it is that native speakers can have the intuitions and make the judgements of well- and ill-formedness that they do.

This last point bears elaborating. One of the surprising facts about our linguistic ability is that it extends to knowing what is impossible as well as what is possible: we have intuitions of ill-formedness or 'negative knowledge'. I have already traded on this fact in assuming that, even though you had probably never heard either example before, you would agree that *Giraffes have necks long* is wrong, whereas *I've just texted an urgent message to Fred* is acceptable. The point can be generalized: the fact that one can recognize mistakes and distinguish them from new but well-formed creations is evidence for the rule-governed nature of the language faculty. Mistakes presuppose norms, or rules. It is also noteworthy that there are 'impossible' mistakes: some logically possible errors just don't happen, even though one might expect them to. Consider an example from language acquisition and the task of the child in working out how questions and statements of the kind in (24) are related:

- (24a) The children are playing truant
(24b) Are the children playing truant?

There are all sorts of hypotheses children might entertain: move the auxiliary (*are*), move the third word, permute the first and second constituents, and so on. The kinds of mistake that children do make, however, show that their hypotheses overlap with these in interesting ways. First, they sometimes make mistakes of a kind for which there is no obvious pattern in the input, even though they may be theoretically well motivated: examples such as the 'auxiliary copying' in (25):

- (25a) Is the steam is hot?
(25b) Are the children are playing truant?

Second, they never try out any hypothesis that would involve them in counting: their attempts always range over modifications of linguistic structure, never of mathematical structure. It seems that all rules in all languages are what is called 'structure-dependent' – they depend on notions such as constituent, Noun Phrase, and so on, but **not** 'third word'. Moreover, children seem not to need to learn this fact – it is a

principle that guides their language acquisition from the start: it is innate. Claims of innateness have been unnecessarily controversial in modern linguistics. No one doubts that humans are innately (genetically) different from cats, chimpanzees, and dolphins, and that this difference underlies our ability to acquire language. Equally, no one doubts that humans acquire different languages depending on the environment they are brought up in: if children are brought up in Turkey rather than Greece, they learn Turkish rather than Greek. It is obvious that both nature and nurture have a crucial role to play. Where controversy is justified, and where empirically different claims can be tested, is in the detail of what needs to be ascribed to the child's 'initial state', of what precisely is innate and what has to be acquired on the basis of experience. Explaining structure-dependence is an area where innateness has been repeatedly (and controversially) defended with a form of argument based on the 'poverty of the stimulus' – the idea that we end up knowing things that it is impossible, or at least implausible, to think that we could find in the input. Consider examples more complex than those above, such as (26):

- (26a) The children who were naughty are playing truant
(26b) Are the children who were naughty playing truant?

If 'moving the third word' or 'moving the (first) auxiliary' were really the correct way of characterizing the relation in (24) one would expect to find example mistakes like that in (27):

- (27a) Who the children were naughty are playing truant?
(27b) Were the children who naughty are playing truant?

Such mistakes simply do not occur. Of course, it is always (usefully) dangerous to say that something does not happen: it may happen in the next utterance one comes across. But this means that the claim is eminently falsifiable (see below), and can anyway be checked by looking for relevant counterexamples in the literature. A nice example of this kind is provided by Neeleman and Weerman's (1997) account of acquisitional differences between Dutch and English. They predicted that Dutch children should, and English children should not, produce sentences with an adverb intervening between a verb and its object, as in (28):

- (28) I will eat quickly the yoghurt

They ransacked the largest international corpus of child data in checking their predictions, and happily found no exceptions.

Formalizing our knowledge of language demands a complex toolkit, only a tiny fraction of which has been given here, but such formalization is a necessary prerequisite to finding explanations, to assimilating linguistics to the scientific enterprise. Given the tools developed here, we can make general hypotheses about the nature of language and begin to test them on a wider range of data from English and elsewhere.

Explanation in Language

Examples involving structure-dependence enable one to address the demand for explanation in addition to description. Let's pursue the issue by looking at the occurrence of items such as *any*, *ever*, or *anything* in English (so-called 'Negative Polarity Items'). At a descriptive level, it is sufficient simply to contrast possible and impossible sentences of the sort seen in (29a) and (29b), where those in (29a) are fully acceptable but those in (29b) are ungrammatical, or infelicitous, or just wrong:

- (29a) John ate something/ some salad
(29b) *John ate anything/ any salad

But *why* is there this contrast? The example in (30) shows that *any(thing)* can occur happily enough in negative statements, but it occurs unhappily in positive statements:

- (30) John didn't eat anything/ any salad

Looking at such negative examples, the generalization seems to be that *any(thing)* needs to occur with (be 'licensed by') a negator. But such an account is inadequate in two different ways: first, (31) shows that it is not just negators that are relevant, but a variety of elements behave in a similar fashion. This class includes questions, conditionals, and other items that there is no space to characterize:

- (31a) Did John eat anything/ any salad?
(31b) If John ate anything/ any salad, I'd be amazed
(31c) Everyone who has any sense has left already
(31d) John denied having eaten any of the cakes

Second, even if we restrict ourselves to negatives, it still seems that life is more complicated than we might wish – (32a) is unsurprisingly fine but, despite being negative, (32b) is unacceptable and none of (32c) to (32e) is acceptable:

- (32a) Something/ some spider bit him in the leg
(32b) *Anything/ any spider didn't bite him in the leg
(32c) *Anything is annoying me
(32d) *Anything isn't annoying me
(32e) *John denied any of the accusations

That is, our first approximation that *any* needs to be licensed by a negative fails in both directions – some

sentences with negatives do not allow *any*; some sentences without a negative do allow *any*. The next obvious assumption might be that *any(thing)* has to be preceded by a negator of some kind (*not* or *n't* here), but (33) shows that this hypothesis is inadequate: it works for (33a) and (33b) but not for (33c) or (33d) – where *nothing* is another negator:

- (33a) The fact that he has come won't change anything
(33b) Nothing will change anything
(33c) *The fact that he hasn't come will change anything
(33d) *That nothing has happened will change anything

The examples in (33a) to (33d) suggest another possibility: perhaps the negator has to be in the same clause as the item (*any*) being licensed? In (33a), the negator and *anything* are in the same clause (compare "*This won't change anything*"), whereas in (33c) and (33d), the negator is in a different clause. We are getting closer, but (34) shows that this is still inadequate as an explanation, as here the negator and *anything* are blatantly in different clauses, but the result is well-formed.

- (34) I don't think he has eaten anything

The claim that the negative (or other item) must be in the same clause as *any* fails: some sentences have the negative in a different clause and are nonetheless grammatical; some have the negative in the same clause and are ungrammatical. The correct explanation necessitates an appeal to the notion of 'c-command,' a relation between 'nodes' in a tree. To make this comprehensible and plausible, we need to introduce a little more of the technical machinery of generative grammar.

The representation of sentence structure in terms of trees of the kind shown in (22) can obviously be extended to show the structure of (29a), as shown in (35), where the only novel feature is the uncontroversial claim that *some* is a kind of Determiner:

More complex sentences require more complex configurations. Thus, the salient property of an example such as (33a) '*The fact that he has come won't change anything*' is that the subject is not just a noun

or noun phrase, but a noun phrase containing another sentence '*he has come*'. To a first approximation it would have the (simplified) form given in (36), and the ungrammatical example in (33c) **The fact that he hasn't come will change anything* would be characterized by the tree given in (37):

Some of the details of the tree have been included for the sake of those who are already familiar with syntax. So the Complementizer Phrase (CP), optionally headed by a Complementizer such as *that*, and the I' (a constituent intermediate in size between a sentence (IP) and an Inflection element like *will*) are there for the *cognoscenti*. But two things in these trees are important for everyone: first, that they contain a constituent Neg(ation), itself a subpart of a NegP(hrase); and second, that it makes sense to talk of one item being higher in the tree than another. That is, in (36), the 'Neg' is higher in the tree than *anything*, whereas in (37) the 'Neg' is lower in the tree than *anything*.

To make this account rigorous, we need to define exactly what is meant by 'higher' and 'lower', and

that is what is meant by 'c-command': a node A in a tree c-commands another node B if and only if the first branching node dominating A also dominates B. In (36), Neg c-commands *anything* because the first branching node above Neg (i.e., NegP) also dominates the NP *anything*; in (37), Neg does **not** c-command the word *anything* because the first branching node above Neg (again NegP) does **not** dominate *anything*.

It may seem as if we are using a sledgehammer to crack a nut, but the beauty of the analysis is that c-command is not just an arbitrary condition introduced to account for a narrow range of data in English. Rather it extends in two directions: it is a major and essential ingredient in the explanation first of a range of other phenomena in English; and second to a wide range of phenomena in other languages, indeed in all languages: **c-command is universal**.

Before illustrating other uses of c-command, note that if it is universal, we would like an explanation for how that is possible. The obvious answer is that it is innate, part of the faculty of language that differentiates humans from other organisms and explains why all kids but no kittens acquire language. If correct, certain implications follow immediately: c-command is not a condition that children acquiring their first language need to learn, rather (like structure-dependence) it acts as a constraint that determines the kind of hypotheses they can come up with in mastering their first language.

Let us look at one generalization of the usefulness of c-command in English: its use in 'binding theory', the part of linguistics that deals with the distribution of pronouns and reflexives. It is a commonplace that reflexive pronouns such as *myself*, *yourself*, *himself*, and so on, have to agree (or 'be compatible') with their antecedent – the entity they refer back to, so the examples in (38) are fine, but those in (39) are ungrammatical:

- (38a) I admire myself
- (38b) The judge admires himself
- (38c) The waitress might flatter herself
- (39a) *I admire yourself
- (39b) *He admires herself
- (39c) *The waitress flattered ourselves

There are all sorts of other interesting complications with reflexives: if there are two possible antecedents, the sentence is ambiguous, so in (40) *herself* can refer to either *the nurse* or *the woman*:

- (40) The nurse showed the woman some documents about herself

but this is true only if the two potential antecedents are in the same clause as the reflexive: (41)

is unambiguous, and *herself* can refer only to *the princess*, because *the queen* is in a different clause:

- (41) The queen said the princess had disgraced
herself

Neither of these extra considerations accounts for why (42a) is unambiguous and (42b) is simply ungrammatical:

- (42a) The mother of the princess has disgraced
herself
(42b) *The brother of the princess has disgraced
herself

The question is why *herself* in (42) can't refer back to *the princess*, but only to the *mother* or the *brother*, resulting in the judgements indicated. The answer is that the antecedent of the reflexive must not only be compatible and in the same clause, but must also c-command it. The structure of possessives such as *the princess's mother* or *the mother of the princess* is a matter of contention, but what is not in dispute is that *princess* is lower in the tree than *mother* or *brother* and hence does not c-command the reflexive: compare the trees in (43a) and (43b) for (38c) and (42a):

In both trees, the underlined DP (*The waitress* in (43a), *The brother/mother of the princess* in (43b)) c-commands *herself*, but the crossed-out DP *The princess* in (43b) does not c-command *herself* so cannot act as its antecedent.

C-command is pervasive in the syntax of English, not just in accounting for polarity items and reflexives. More strikingly, it is pervasive in the syntax of

every other human language. Consider (Cantonese) Chinese. Cantonese has a rich selection of sentence-final particles with a wide range of meanings from conveying a feeling of intimacy to indicating which element in the preceding sequence is the focus. In English, we can indicate this focus by means of stress, giving rise to the kind of difference in (44a) and (44b):

- (44a) John only **watches** football (he doesn't play it)
(44b) John only watches **football** (not cricket)

It's even possible, with suitable pause and stress, to have (45b) with the same interpretation as (45a):

- (45a) Only **John** watches football (not Bill)
(45b) **John** only, watches football (not Bill)

Just as in English, Cantonese uses stress to identify the intended focus from the set of possible foci, and the operator *zaa3* (*only*) then associates with this intended focus, as in (46), which can have the various interpretations shown in (47):

- (46) Billy tai zukkau zaa3
Billy watch football zaa3
(47a) Only **Billy** watches football (not Peter)
(47b) Billy only **watches** football (he doesn't play it)
(47c) Billy only watches **football** (not cricket)

There is good evidence (see Law, 2004) that *zaa3* occurs in some C position of the sentence, and hence c-commands everything preceding it in the example in (46): see the tree in (48), (C is arguably final in Cantonese, not initial as it is in English):

But to talk simply in terms of linear precedence or word order is inadequate. Cantonese also has a process of topicalization whereby a constituent – e.g., *zukkau* ('football') – can be moved to the front of the sentence, where it is attached even higher in the tree than *zaa3*, and marked with *le1* (the 1 indicates a high level tone). This is shown in (49a), with a range of putative translations in (49b) to (49d). Crucially, as indicated by #, (49d) is **not** a possible interpretation of the Cantonese sentence.

- (49a) zukkau-le1, Billy tai t zaa3
(49b) Football, only Billy watches

- (49c) Football, Billy only watches
 (49d) #Only football does Billy watch

Why this should be so is indicated in the tree in (50), where *zukkau* is not c-commanded by *zaa3*: (The ‘t’ for ‘trace’ in (48a) and (49a) indicates where the topicalized constituent *zukkau* moved from).

Because *zaa3* does not c-command *zukkau*, the attempted interpretation in (49d) is simply impossible. The examples are extremely simple, indeed extremely oversimplified, but the moral is clear: the same abstract syntactic condition (c-command) operates in Chinese just as it does in English, and in every other language.

It is worth emphasizing that successful explanations for one class of data are good to the extent that they generalize to phenomena for which they were not devised. C-command was not invented to account for Chinese, but the fact that it automatically accommodates quite subtle data in that language lends support to a theory that incorporates it. The point can be illustrated more widely. Every time one draws a tree of the kind illustrated above, one makes predictions about the well-formedness of a host of other sentences. It is striking that the trees in (36) and (37) exhibit a defining property of human language – its recursive power. That is, the possibility of including one sentence inside another sentence, potentially without limit, gives rise to the infinite expressive power of natural language syntax.

Linguistics as a ‘Science’

Making testable predictions of this kind is one of the hallmarks of science, and we can now elaborate on the claim that linguistics is ‘scientific’. For any discipline to be scientific it must satisfy (at least) the conditions in (51):

- (51a) It must seek **explanation**
 (51b) It must pursue **universals**

- (51c) This will necessarily involve **idealization** which may well give rise to a tension between commonsense and science
 (51d) Most crucially, it will make **falsifiable predictions**

The scientific enterprise is a search for explanatory laws or principles. That is, linguists – like physicists or molecular biologist – seek not only data, but also data that can be used as **evidence** for some theoretical claim. Consider again the analysis of reflexives. Early work in linguistics of the sort best exemplified by the work of Bloomfield (1935) provided detailed exemplification of a wide range of reflexive constructions from a variety of languages, but stopped short of trying to explain their distribution. One of the achievements of generative grammar has been precisely to explain – in terms of ‘binding theory’ – why reflexive pronouns have the distribution they do. To elaborate a little on the discussion given already under the ‘Explanation in Language’ section, the appearance of a reflexive pronoun is determined by principle A of binding theory which says that a reflexive must be ‘bound’ in some domain. As we saw, this means that it must have an antecedent which also meets a number of other conditions. Principle A is in contrast with Principle B, which determines the distribution of ‘ordinary’ pronouns. That is, between them the principles account for the range of facts discussed above as well as for the contrast between *John admires him* and *John admires himself*; why one can construe *John* and *him* as referring to the same person in (52b) but not in (52a), even though the latter seems to include the former as a proper subpart, and a host of other facts:

- (52a) John expects to see him
 (52b) I wonder who John expects to see him

Evidence for – or against – the claims of binding theory, or any part of the theoretical edifice, can be drawn from a wide variety of domains: the distribution of words in sentences; the acquisition of their first language by children, and of second and subsequent languages by both children and adults; the historical change of language over time; the processing of language – be it production or perception – in normal and abnormal circumstances; the problems that arise in pathology, as a result of language disturbance caused by a stroke or a tumor, and so on. In every case, explanation calls for concentration on those data that can provide evidence: the data themselves are trivial until embedded in a theory that can produce testable hypotheses.

A concomitant of this search for explanation is that the generalizations made must carry over in relevant ways to all languages, not just to English or Latin or

Chinese. That is, the quest for laws entails that any science must pursue *universals*, even if that means narrowing the domain of inquiry. This position has two implications: first, that the same principles should apply to Dutch and Hindi and Chinese – so ‘all languages’ is to be construed literally; but second, that the domain of application of these principles may not be superficially obvious. To take the second observation first, it is well-known that there are so-called ‘emphatic’ reflexives, as illustrated in (53a) and (53b), which raise difficulties for any simple analysis of reflexivization in general:

(53a) John himself came

(53b) John came himself

These ‘reflexives’, so labeled because they include the morpheme {*self*}, have somewhat different properties from ‘real’ reflexives: for instance, they don’t have any thematic role, (*came* takes only one argument – you can’t ‘come somebody else’), but simply emphasize the importance of the one role mentioned. On the other hand, they clearly do obey some of the same constraints as ordinary reflexives, as witness the peculiarity of the examples in (54):

(54a) *The boy came herself

(54b) *The boy’s mother himself came

This duality suggests that it might be necessary – as a temporary measure – to limit the domain of binding theory to arguments taking a thematic role, leaving the emphatic examples to be accommodated later after further research. The situation is parallel to the development of a scientific theory of motion. For Aristotle, all motion fell within the ambit of his theory of movement, even the movement of flowers growing. Galileo was able to provide a unified account of terrestrial and heavenly motion by restricting attention to mechanical motion and excluding biological growth. This should not be viewed as a retreat to a position where whatever you say turns out to be true, simply because you have excluded those areas where what you say is false. Rather it is an attempt to define an area where we can begin to understand the complexity of the real world by focusing on phenomena that are comprehensible.

This narrowing is of two kinds: first, one can simply ignore data which fall outside the generalization one is attempting to explain; second, there is scientific idealization – the pretence that things are simpler than they really are. This is justified because such simplification enables one to approach an understanding of the abstract principles which underlie complex phenomena. Such idealization in linguistics was first made explicit in Chomsky’s distinction between competence and performance and his claim

that “linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech-community.” We all know that real speech communities are not homogeneous, but the force of the idealization is that the heterogeneity that does exist is not a necessary component in an adequate characterization of our knowledge of language or how we come by that knowledge. Consider in this latter respect the simplifying assumption – the striking idealization – that first language acquisition is ‘instantaneous’. It is obvious that children take a considerable time to master the intricacies of their first language. Given how complex the knowledge they end up with is, it may still be justifiable to talk of the surprising speed with which they reach this mastery, but it is **not** by any stretch of the imagination ‘instantaneous’. So what is the force of the assumption? Consider the acquisition of negation.

Most, perhaps all, children go through a stage in which they produce negative sentences with the negative marker (*no* or *not* in English) in peripheral position in the sentence – i.e., first or last – as in (55a) and (55b), heard from two different two-year-olds:

(55a) No computer on

(55b) Computer on no

The context made it clear in each case that the force of the utterance was an order not to turn the computer on. Superficially, it looks as if the two children have different grammatical systems (though they were equally proficient at understanding adult instructions, suggesting that their grammar was more sophisticated than might appear). What is relevant here, however, is the fact that – as far as is known – both children will end up with the same grammatical knowledge of English negation. That is, the different stages they go through in their acquisition of the details of the grammar has no effect on the knowledge they end up with – their adult competence. This claim may, of course, be false. It might turn out that adults who uttered (55a) as children have different grammars from those who uttered (55b) as children. It’s possible, but there is no evidence to that effect, and the idealization to instantaneity is accordingly justified. If one of the things we wish to explain is how humans can progress from a stage in which they are apparently language-less to a stage of adult knowledge, it is advantageous to be able to abstract away from the different paths they may take in acquiring that knowledge. The idealization also simplifies the account of the initial state of the language faculty: what needs to be attributed to the mental make-up of human infants to explain the fact that they do, while infant chimps do not, acquire language.

Idealization of this kind is in turn likely to involve a tension between commonsense and science. The claim of instantaneous language acquisition seems blatantly silly until one considers more carefully what it means. Consider a second example, again from first language acquisition. Children regularly mispronounce the words they are learning, sometimes with surprising results, as in the case of the puzzle *puddle*. When he was about two and a half, my son – like many children – used to pronounce *puddle* as ‘puggle’ ([pʌgəl]). He was perfectly consistent, and used to pronounce words of a comparable kind with the same kind of deformation: so *bottle* became ‘bockle’, *pedal* became ‘peggle’, and so on. The obvious explanation for this behavior was that, for reasons of motor control, he was unable to pronounce *puddle*. But at the same time as he made this mispronunciation, he was also making ‘mistakes’ with words such as *zoo*, pronounced as ‘do’, *lazy*, pronounced as ‘lady’, and so on. The result was striking: although he pronounced *puddle* as ‘puggle’, he consistently pronounced *puzzle* as ‘puddle’ ([pʌdəl]), so the reason for the former ‘mistake’ could clearly not be that he was incapable of the appropriate motor control. He could pronounce ‘puddle’, but only as his version of *puzzle* not for *puddle*. So the commonsense explanation of the phenomenon was wrong. An obvious alternative explanation was that he couldn’t hear the difference, but that hypothesis wasn’t much more plausible either, as his pronunciations of the two words were consistently different, indicating that he must be able to perceive the contrast. So the second ‘obvious’ commonsense explanation was equally problematic. The correct explanation was provided by Marcy Macken, who demonstrated that there was a perceptual problem, but not between *puzzle* and *puddle*, but rather between *puddle* and *puggle*. Of course, *puggle* is not a word of English, so I had failed to observe relevant examples. Words like *riddle* and *wriggle* provide a straightforward minimal pair, but they had not been in my son’s vocabulary. Fortunately, Macken observed that other examples made the case as well as the (missing) minimal pair did. Words such as *pickle* were intermittently pronounced ‘pittle’ ([pitʔl]) suggesting that there was indeed perceptual confusion. The puzzle *puddle* could only be solved when the difference between a variety of other examples was simultaneously taken into account.

I have gone on about this example at such length because it illustrates the beauty of being (potentially) wrong. The most crucial part of the scientific enterprise is that it makes testable (or ‘refutable’ or ‘falsifiable’) predictions. Because my son regularly distinguished *puddle* and *puzzle*, and similar examples, I had claimed explicitly that he had no

perceptual problem. Macken showed that I was wrong and, on the basis of my own data, showed how I was wrong, leading to an improvement in our general understanding of language acquisition, and the language faculty more generally. Such falsifiability is pervasive in linguistics as in all the sciences, and suggests that many, perhaps all, our hypotheses and principles will be in need of revision when we get a better understanding of what is going on. It follows that binding theory, which I have appealed to above, is probably wrong, and will need replacing by some more sophisticated theory in due course. Again this is to be welcomed, though we must simultaneously guard against the danger of ‘naive falsificationism’. There are always going to be contrary data that one’s current theory cannot explain. This is not a reason for simply jettisoning the theory and whatever insights it may provide, but a point of departure for refinement and extension. A clear example is provided by the theory of parametric variation, and the striking revision of his earlier work in Chomsky’s current Minimalist Program (1995).

I have suggested that, like all principles of grammar, binding theory should be universal. But there are problems. Even though (virtually) all languages have reflexives, their distribution is subject to slightly different conditions in different languages. Consider again the contrast between (40), *The nurse showed the woman some documents about herself*, and (41), *The queen said the princess had disgraced herself*, where the former is ambiguous but the latter is unambiguous. The contrast was attributed to the fact that (in English) the antecedent of a reflexive must be in the same clause. So far so good, but if one takes equivalent examples in Chinese, it turns out that the equivalent of (40) is unambiguous, and the equivalent of (41) is ambiguous. The theory would appear to have been refuted: a prediction was made, it was tested, and found to be false. But simply giving up the theory would be defeatist, and it would also mean giving up the explanation for the data it does account for.

The solution is interesting: the universality of binding theory (and likewise for other subtheories of the grammar) is maintained, but some latitude is allowed in the definitions involved – they are ‘parametrized’, as the jargon has it. In this case, all reflexives have to have an antecedent, but language learners have to choose (on the basis of the data they are exposed to) among several other options: whether they are learning a language in which that antecedent has to appear in the same clause or in some other well-defined domain; whether the antecedent has to be a subject or can bear other grammatical relations, and others. In Chinese, the antecedent of a reflexive must be a subject, so (40) is unambiguous; on the other

hand, that antecedent does not have to be in the same clause, so (41) is ambiguous. If you are worried that this is too simple a get-out, an analogy with incest may be helpful: all cultures appear to have an incest taboo forbidding sexual relations between relatives (for instance, fathers and their daughters). The taboo is universal. But how that taboo is instantiated is culture-specific: for example, some groups allow cousins to marry, others do not. The situation with regard to language and language-learning is somewhat more complex than the cultural example, because there are many more choices to be made. The acquisitional task is more complex than it would have been if all languages were exactly like English, but it is not as severe as one might fear. The idea is that the full range of parametric choices in language is available to the child prior to experience – they are in some sense innate – and the child's task reduces to choosing from a set of language structures options it already 'knows.'

Beyond Language: Pragmatics and the Language of Thought

We have looked at a wide range of examples illustrating some of our knowledge of phonology, morphology, semantics, and (mainly) syntax, but we also have knowledge that goes beyond words and sentences. Consider (56a) and (56b): as a remark about Fred, (56a) is fine, with stress on *bats* as indicated by the bold print, but as a reply to the question in (56b) it is anomalous:

- (56a) Fred has written a book about **bats**
 (56b) Who has written a book about bats?

Such discursual knowledge must be distinguished both from syntactic knowledge of the kind that tells us that (57) is ungrammatical:

- (57) Fred has written about **bats** a book

and from real world knowledge of the kind that prompts our scepticism about (58a) and (58b):

- (58a) Bananas have legs
 (58b) Your saucer is being aggressive again

Someone who utters (56a) in response to (56b) probably needs remedial English lessons; someone who utters either of the sentences (58a) or (58b) is either a linguist or in need of psychiatric help.

This brings us into the realm of pragmatics, our interpretation of utterances in context, and to the relation of language to thought. The examples in (58a) and (58b) are felt to be odd not because of our linguistic knowledge – you get the same effect whatever language you translate them into – but

because we know that the world isn't like that. It is our encyclopedic knowledge that tells us this, not knowledge of our language (English). However, when we interpret someone's utterances in some context, we habitually use both our knowledge of English (or whatever other language we are using) and our encyclopedic knowledge. Suppose you hear (3a) *Tom is a problem*. Your knowledge of English vocabulary and grammar provides you with a meaning for the sentence, but it doesn't tell you enough to act. Is your interlocutor looking for sympathy, asking you to do something about it, hoping for a denial? Any or all of these may be what you decide is the case on a particular occasion, but you carry out this construal on the basis of your knowledge of the speaker, of Tom, of your past exchanges with both of them, and so on, indefinitely. The core notion involved is what is 'relevant', an idea that has been made explicit in Relevance Theory, an important extension of linguistics. We are now beyond the language faculty and can hand over responsibility to other disciplines; but one final question needs to be addressed: What is language for?

There are two standard answers: for thought and for communication. Both answers are true, but both need a little hedging. First, we can obviously communicate without using language by means of coughs, sniffs, gestures, and so on. But language is far more subtle than any other system known: conveying specific negative or conditional propositions by means of gestures or sniffing is not obviously possible. Innumerable other creatures have complex communication systems, but none of them, as far as we know, have anything with the recursive power of human syntax (see Sperber and Wilson, 1995; Hauser *et al.*, 2002). Second, the system we use to think with must have a great deal in common with the natural languages we speak, but it is not identical to them. The language of thought can include elements that natural languages cannot – visual images, for instance; and natural languages have properties that would be unnecessary, or even unhelpful, in the language of thought – pronouns, for instance. If I tell you that *she is beautiful*, it's of no use to you storing that in memory as 'she' is beautiful; it has to be stored with a name or some other description replacing *she*. Nonetheless, language has a central role in each of these domains, linking perception and articulation on the one hand to thought processes on the other. This means that the output of our language faculty must be 'legible' to these other systems. Language acts as a code linking representations of sound to representations of meaning. These representations must then be in a form that makes it possible for the sensorimotor apparatus to convert them into pronunciations and

percepts, and for the conceptual system to use them for thinking, especially inference.

So, linguistics provides an account of each of syntax, phonology, morphology, and semantics, and how they relate to each other; pragmatics then tells us how such purely linguistic representations relate to the language of thought – the medium in which we think and carry out inferencing. This relation underlies our ability to interpret the world and the people in it, but the linguistic component is only the first step on the journey. We normally take someone who utters ‘torture is immoral’ to *believe* that torture is immoral, and we expect to be able to predict (at least some of) their actions on the basis of this. But people may lie, and about that linguistics has nothing to say.

Logic and Language: Philosophical Aspects

G Callaghan, Wilfrid Laurier University, Waterloo, Ontario, Canada

G Lavers, University of Western Ontario, London, Ontario, Canada

Introduction

Theories of meaning and methods of linguistic analysis are key items in the agenda of contemporary analytic philosophy. Philosophical interest in language gained substantial impetus from developments in logic that took place in the latter half of the nineteenth century. It was at this time that the early modern conception of logic as an informal ‘art of thinking’ gave way to the contemporary conception of logic as a formally rigorous, symbolic discipline involving, *inter alia*, a mathematically precise approach to deductive inference. The systems of symbolic logic that emerged in the later stages of the nineteenth century were fruitfully applied in the logical regimentation of mathematical theories – analysis and arithmetic in particular – and logical analysis became the cornerstone of a general philosophical methodology for a number of influential figures in the first half of the twentieth century. Though the operative conception of logical analysis did not in every case treat language (or ‘natural language’) as the proper object of investigation, close connections between logic and language were stressed by virtually every proponent of the methodology. Our aim in this entry is to discuss these connections as they appear in the work of some of the eminent precursors and purveyors of the analytic tradition.

The Mathematicization of Logic: Leibniz and Boole

Early modern philosophers were typically antipathetic to the formal approach to logic embodied in Aristotle’s doctrine of the syllogism and its Scholastic variants. Among the major figures of the early modern period, Gottfried Wilhelm Leibniz (1646–1716) is distinguished both for his respect for the Aristotelian tradition in logic and for his general emphasis on the importance of formal methods. Leibniz applauded Aristotle for being “the first to write actually mathematically outside of mathematics” (1696: 465). However, it was Leibniz’s own works, rather than those of Aristotle or of contemporary Aristotelians, that in the period did most to advance the conception of logic as a kind of generalized mathematics.

Leibniz’s logical work consists of a number of manuscripts, unpublished in his lifetime, in which he undertakes the construction of a logical calculus. In virtually all of these works, Leibniz represents judgments and logical laws in a quasi-arithmetical or algebraic notation and he assimilates processes of inference to known methods of calculation with numbers (e.g., by substitution of equals). Leibniz’s motivation for this approach stemmed from his early project of a *lingua characteristica universalis* – a symbolic language geared to the logically perspicuous representation of content in all fields of human knowledge. According to Leibniz, the content of any judgment consists in the composition of the concepts arrayed in the judgment as subject and predicate. A judgment is *true* when the predicate concept is ‘contained in,’ or partially constitutive of, the subject concept. For example, the truth of the judgment that all men are rational consists in the fact that the concept *rational* is contained in the concept *man*, as per the traditional definition of ‘man’ as ‘rational animal.’ (For obvious reasons, Leibniz’s conception of truth posed difficulties when it came to accounting for contingently true judgments, and the task of providing an account of contingency compatible with his conception of truth was one to which Leibniz devoted considerable philosophical attention.) All complex concepts can be parsed as conjunctions of concepts of lower orders of complexity down to the level of simple concepts that cannot be further analyzed. Leibniz’s various schemes for a universal characteristic were predicated on the idea that containment relations among concepts could be made arithmetically tractable given an appropriate assignment of ‘characteristic numbers’ to concepts. For instance, in one such scheme Leibniz proposed that the relationship between complex concepts and their simple constituents be represented in terms of the relationship between whole numbers and their prime factors, thus capturing the unique composition of any complex from its primitive components (1679, 1679/1686). In this and similar ways, Leibniz sought to provide a basis for the view that inference, and the evaluation of truth more generally, could be carried out algorithmically – that is, as a mere process of calculation – by familiar arithmetical means.

By the 1680s Leibniz had grown pessimistic about the prospect of completing the project of the universal characteristic, and he turned his energies to the more confined task of devising an abstract logical calculus. Leibniz worked on a number of different versions of his logical calculus through the 1680s and 1690s. In each case he explained how standard propositional

forms could be expressed in a quasi-algebraic notation. He also laid down logically primitive laws pertaining to his formulas (what he called ‘propositions true in themselves’) and abstractly specified valid inferential transformations, usually in terms of a definition of ‘sameness’ in conjunction with principles pertaining to the substitutability of identicals. Though Leibniz’s efforts at constructing a logical calculus were hampered by his view that all judgments ultimately reduce to a simple subject-predicate form – thus excluding primitive relational judgments – his emphasis on formal explicitness and mathematically exact symbolism stands as an anticipation of the main lines of development in formal logic in the following centuries.

Leibniz’s mathematical approach to logic made little impression until the late nineteenth century, when his manuscripts were finally collected and published. By that time, however, the mathematical approach had gained momentum independently, largely on the basis of the work of George Boole (1815–1864). Boole shared with Leibniz the aim of devising an algebraic means of expressing relationships among terms figuring in propositions. However, Boole differed from Leibniz in treating the extensions of concepts (or classes), rather than concepts construed as attributes or ‘intensions,’ as the relevant propositional constituents. In *The laws of thought* (1854), Boole presented his class logic, which he called ‘the logic of primary propositions,’ as the first and fundamental division of his system. In the second part of the same work, Boole adapted the calculus of classes to a special interpretation that allows for the representation of logically compound propositions, or ‘secondary propositions,’ thereby unifying (after a fashion) the calculus of classes with a version of modern propositional calculus.

Boole’s central idea is that an algebra of logic arises as an *interpretive variant* of standard numerical algebra when the latter is modified by a single principle that is naturally suggested by the logical interpretation of the symbolism. In Boole’s class logic, letters (or ‘literal symbols’) are interpreted as standing for classes of things determined by some common attribute, with ‘1’ standing for the universe class and ‘0’ standing for the null class. Multiplication, addition, and subtraction operators are treated as standing for the operations of intersection, disjoint union, and difference (or ‘exception’) of classes, respectively. Primary propositions are then expressed as equations with appropriately formed class terms standing on either side of the identity sign. On the basis of this class-theoretic interpretation of the symbolism, Boole maintained that the logical calculus differs from ordinary numerical algebra only with

respect to the characteristically *logical* law that, for any class x ,

$$xx = x \text{ (} x \text{ intersect } x \text{ is } x \text{)}$$

which holds generally for class theoretic intersection but which holds for numerical multiplication only for $x = 0$ and $x = 1$. Having emphasized this difference, Boole observed that the laws and transformations of numerical algebra will be identical to those of an algebra of logic when the numerical values of literal symbols in the former are restricted to 0 and 1. Boole appealed to this formal analogy between the numerical and logical algebras in justifying his approach to inference, which he presented as a process of solving sets of simultaneous equations for unknowns by standard algebraic methods.

In *The laws of thought*, Boole transformed the calculus classes into a serviceable propositional calculus by interpreting his literal symbols over ‘portions of time’ during which elementary propositions are true, thus adapting the notation and methods designed for dealing with class relationships to the propositional case. Boole’s appeal to portions of time reflected a somewhat puzzling endeavor to assimilate or reduce propositional logic to the kind of term logic embodied in his class calculus, and the artificiality of this approach was not lost on subsequent logicians both within and without the algebraic tradition. However, peculiarities of interpretation notwithstanding, Boole can be credited with the first systematic formulation of propositional logic and a commensurate expansion of the scope of formal logic in general. Moreover, his suggestion that propositional logic, class logic, and numerical algebra (suitably restricted) arise as interpretive variants of a single algebraic system anticipates subsequent developments in abstract algebra and (perhaps only dimly) modern model-theoretic methods in logic.

The contributions of Leibniz and Boole constitute beginnings in the fruitful deployment of artificial languages in the analysis of propositional content and the systematization of deductive inference. However, despite their considerable accomplishments, neither Leibniz nor Boole can be credited with bringing logic to its current state of maturity. They produced no inroads in the logic of relations and the use of quantifiers for the expression of generality is entirely foreign to their work. These shortcomings were addressed by later logicians working in the algebraic tradition (e.g., Pierce and Schröder), but the significance of their resolution for the development of modern formal logic and its philosophical offshoots will be better appreciated if we adopt a somewhat different perspective on the historical interplay between logic and mathematics.

Logic and Language in Frege

For the better part of his career, the philosopher-mathematician Gottlob Frege (1848–1925) devoted his energies to establishing the ‘logician’ thesis that arithmetical truth and reasoning are founded upon purely logical principles. At an early stage in his efforts, Frege realized that existing systems of logic were inadequate for carrying out the analysis of content necessary for establishing arithmetic’s logical character. His *Begriffsschrift* (or ‘concept notation’) (1879) was intended to address this deficiency. The logical system that Frege presented in the *Begriffsschrift* and later refined in Part I of his *Grundgesetze Der Arithmetik* (1893) constitutes the greatest single contribution in formal logic since the time of Aristotle. The most distinctive aspects of Frege’s logic are (1) the use of variables and quantifiers in the expression of generality; (2) the assimilation of predicates and relational expressions to mathematical expressions for functions; (3) the incorporation of both propositional logic and the logic of relations within (second-order) quantificational logic; (4) the notion of a formal system – i.e., of a system comprising a syntactically rigid language along with explicit axioms and inference rules that together determine what is to count as a *proof* in the system.

Frege’s approach to generality is based on his analysis of predication in terms of function and argument. In arithmetic, a term such as $7 + 5$ can be viewed dividing into function and argument in different ways. For instance, it can be treated as dividing into the function $() + 5$ with 7 as argument, or as dividing into the function $7 + ()$ with 5 as argument, or as dividing into the binary function $() + []$ with 7 and 5 (in that order) as arguments. Frege’s approach to predication assimilates the analysis of sentences to this feature of the analysis of arithmetical expressions. For example, a simple sentence such as ‘John loves Mary’ can be regarded as predicating the (linguistic) function ‘ $()$ loves Mary’ of the singular term ‘John,’ or the function ‘John loves $()$ ’ of the singular term ‘Mary,’ or the relational function ‘ $()$ loves $[]$ ’ of ‘John’ and ‘Mary’ (in that order). In the *Begriffsschrift*, Frege remarked that, for simple sentences like this, the analysis into function and argument makes no difference to the ‘conceptual content’ that the sentence expresses. However, the *possibility* of analyzing a sentence in these ways is nevertheless crucial to logic, since only on this basis do we recognize logical relationships between generalizations and their instances. Adopting a standard arithmetical practice, Frege makes use of variables as a means of expressing generality. For example, by putting the variable ‘ x ’ in the argument-place of ‘Mary’ in our example, we

arrive at the statement ‘John loves x ,’ which is the *Begriffsschrift* equivalent of the colloquial generalization ‘John loves all things.’ The inference from this generalization to ‘John loves Mary’ now *requires* that we regard ‘Mary’ as argument to the function ‘John loves $()$,’ since only so is ‘John loves Mary’ recognizable as an *instance* of the generalization. Other function-argument analyses become salient in connection with other generalizations to which the statement relates as an instance (e.g., ‘ x loves Mary’).

In the system of the *Begriffsschrift*, the above described use of variables suffices to express generality in a limited variety of sentential contexts. However, Frege’s broader treatment of generality involves a second crucial component, namely, the use of quantifiers – i.e., the variable binding operators ‘ $\forall x$ ’ (read: ‘Every x ’) and ‘ $\exists x$ ’ (read: ‘some x ’) – as a means of indicating the *scope* of the generality associated with a variable. (Our discussion here prescind from the peculiarities of Frege’s now obsolete notation as well as his convention of treating existential quantification in terms of universal quantification and negation – i.e., his treatment of ‘ $\exists x \dots$ ’ as ‘ $\sim \forall x \sim \dots$ ’). One of the many ways in which the use of quantifiers has proven important to logic concerns the expression of multiply general statements, for which no adequate treatment existed prior to the *Begriffsschrift*. Consider, for example, the relational generalization ‘Everyone loves someone.’ This statement is ambiguous between the following two readings: (1) ‘There is some (at least one) person that is loved by all,’ and (2) ‘Every person is such as to love some (at least one) person.’ The use of quantifiers resolves this ambiguity by requiring that expressions of generality in multiply general statements be ordered so as to reflect scope. The first reading of the statement is expressed by the existentially quantified sentence

$$\exists y \forall x xLy$$

where the scope of universal quantifier falls *within* that of the existential quantifier. (For convenience, we assume here that the variables ‘ x ’ and ‘ y ’ are restricted to a domain of persons.) By contrast, the second reading is given by the sentence

$$\forall x \exists y xLy$$

where the universal quantifier has wide scope with respect to the existential quantifier. Since the *Begriffsschrift*’s formation rules ensure that the scope of a quantifier will be properly reflected in any sentence in which it occurs, an ambiguous sentence such as the one we started with cannot even be *formulated* in the language. Scope considerations apply in essentially the same way to sentential operators (e.g., the negation sign ‘ \sim ,’ and the conditional

sign ‘ \rightarrow ’) in the logic of the *Begriffsschrift*. For instance, the ambiguity of the sentence ‘Every dog is not vicious’ results from the fact that, as stated, the sentence does not determine the scope of the negation sign with respect to that of the universal quantifier. On one reading, the scope of the negation sign falls within that of quantifier, i.e., ‘ $\forall x(Dx \rightarrow \sim Vx)$,’ the statement thus affirming that anything that is a dog is not vicious (or, colloquially expressed: ‘No dogs are vicious’). By contrast, when the statement is read as giving wide scope to the negation sign, i.e., ‘ $\sim \forall x(Dx \rightarrow Vx)$,’ it becomes the denial of the generalization that all dogs are vicious (i.e., ‘It is not the case that all dogs are vicious’). As the above examples begin to suggest, Frege’s technique of ordering of operators according to scope provides the basis for his incorporation of both propositional logic and the logic of relations within quantificational logic.

Frege’s philosophical interest in language extended beyond his characterization the formal mechanisms of a logically perspicuous language such as the *Begriffsschrift*. In the classic paper ‘On Sense and Reference’ (1892), Frege presented a framework for a general theory of meaning applicable to both natural languages and formal languages. The core of the doctrine consists in the contention that any adequate account of the meaning of a linguistic expression must recognize two distinct, but related, semantic components. First, there is the expression’s *reference*, i.e., its denotative relation to a *referent* (or denoted entity). Second, there is the expression’s *sense*, which Frege characterized as a particular manner in which the expression’s referent is cognitively presented to the language user. Frege motivated this distinction by drawing attention to sentences in which the meaning of a singular term is apparently *not* exhausted by its correlation with a referent. For example, if the meaning of a singular term were to consist only in what it refers to, then the true, but non-trivial, identity statement ‘The evening star is the morning star’ could not differ in meaning from the *trivially* true identity statement ‘The evening star is the evening star.’ Since the latter statement results from the former by substituting co-referential singular terms, any view that equates meaning with reference will necessarily fail to register any difference in meaning between the two statements. But the two sentences clearly *do* differ in meaning, since ‘The evening star is the morning star’ is not a trivial identity, but an informative identity – indeed, one that expresses the content of a genuine astronomical discovery – whereas ‘The evening star is the evening star’ is plainly trivial. Frege accounts for this by suggesting that while ‘the evening star’ and ‘the morning star’ have a common referent, they express different senses.

A language user therefore grasps the common referent differently in connection with each of the two expressions, and this in turn accounts for the difference in ‘cognitive value’ between the two identity statements. Frege applies the notion of sense to similar effect in addressing puzzles concerning the meaning of singular terms in so-called ‘intensional contexts,’ for example, belief reports.

In subsequent writings, Frege extended the sense-reference distinction beyond the category of singular terms (which, on Frege’s account, refer specifically to ‘objects’), to *all* categories of linguistic expression, including monadic and polyadic predicates (which refer to ‘concepts’ and ‘relations,’ respectively), and complete sentences. In the case of sentences, Frege identified as referents the two truth-values, ‘the true’ and ‘the false,’ and he characterized these as special ‘logical objects.’ A sentence’s sense is, by contrast, the ‘thought’ it expresses, where the thought is understood as a compositional product of the senses of the sentence’s linguistic subcomponents. As strained as this extension of the theory may appear, particularly with respect to reference, it brings to light two important features of Frege’s approach to meaning. First, it reflects his insistence that the theory of reference should comprise, *inter alia*, a theory of *semantic value* – that is, a systematic account of how the semantic values of complex expressions (which, in the case of sentences, are truth-values) are determined on the basis of the semantic values of their subordinate constituents. Second, it reflects an endeavor to integrate the theory of semantic value with a plausible general account of *linguistic understanding* (as given by the theory of sense). Seen in light of these general ambitions, Frege’s theory of sense and reference proposed an agenda that any comprehensive approach to the theory of meaning must in one way or another respect – a point that is amply borne out by subsequent developments in analytic philosophy of language.

Russell: Definite Descriptions and Logical Atomism

The idea that logical analysis forms the basis of a general philosophical method is central to the philosophy of Bertrand Russell (1872–1970). It is especially prominent in the works Russell produced over the first quarter of the twentieth century. In this period, Russell developed and defended the doctrine of ‘logical atomism,’ which grew out of his attempt to establish a version of logicism in the philosophy of mathematics, and came to encompass a wide variety of semantic, metaphysical, and epistemological ambitions. The common thread in Russell’s approach

to these matters consists in his emphasis on logical analysis as a method for clarifying the ontological structure of the world and the epistemological basis of our knowledge of it. As Russell put it, “the atom I wish to arrive at is the atom of logical analysis, not physical analysis” (1918: 37). Bound up with the notion of a logical atom, understood as a basic residue of logical analysis, is the notion of logical structure itself. Our aim in this section is to illuminate Russell’s conception of logical structure, or ‘logical form,’ as it emerges in his theory of linguistic meaning and in his broader atomism.
